Many of the drugs used in treating rheumatic diseases provide relief from pain and inflammation, with hopes of controlling symptoms rather than providing a cure. Analgesics such as acetaminophen (Tylenol) are effective pain relievers. Drugs commonly used to reduce inflammation affect the synthesis of PGs by inhibiting COX activity, thus diminishing PG production. Glucocorticoid therapy decreases the release of ARA from cell membrane phospholipids by binding to the receptor in the cell cytoplasm. This forms a complex that moves into the nucleus as a transcription factor and interferes with expression for the enzyme phospholipase.

Nonsteroidal antiinflammatory drugs (NSAIDs), which include ibuprofen (Advil or Motrin) and naproxen (Aleve), slow down the body's production of PGs by inhibiting COX-1 enzyme activity. They are considered useful tools in the management of most rheumatic disorders; however, long-term use of NSAIDs may cause gastrointestinal problems such as gastritis, ulcers, abdominal burning, pain, cramping, nausea, gastrointestinal bleeding, or even renal failure (Table 40-2; see Chapter 9 and Appendix 31). COX-2 inhibitors (COX-2 selective NSAIDs) such as celecoxib (Celebrex) have been shown to provide relief comparable to other NSAIDs with potentially less gastrointestinal and cardiovascular toxicity. Naproxen and celecoxib appear to be safer than other NSAIDs (Food and Drug Administration, 2005).

**Biologic response modifiers** are a class of drugs that selectively target different elements of the disease, and include those directed against interleukin (IL)-1 such as anakinra (Kineret), or against tumor necrosis factor (TNF)- $\alpha$ , like adalimumab (Humira), etanercept (Enbrel), and infliximab

(Remicade). These molecules are administered by injection (vein or subcutaneous) because they are proteins and oral administration would destroy their biologic activities. The main drawback is their high cost, as high as \$30,000 dollars per patient per year (American College of Rheumatology [ACR], 2006). Patients taking these drugs should be monitored for chronic infections.

Corticosteroids (cortisone [Cortone], prednisone [Delta-sone], methylprednisolone [Medrol], and hydrocortisone [Cortef]) suppress the immune system and decrease inflammation, making them desirable treatments for many of the rheumatic diseases. Possible side effects of corticosteroids include hypertension, hyperglycemia, weight gain, and osteoporosis. Low-dose steroids control most of the inflammatory features of early polyarticular RA. Dehydroepiandrosterone (DHEA), a hormone made by the adrenal glands, has failed to show efficacy.

As the most potent of the antiinflammatory drugs used to treat RA, steroids have extensive catabolic effects that can result in negative nitrogen balance. Hypercalciuria and reduced calcium absorption can increase the risk of osteoporosis (see Chapters 9 and 25). Concomitant calcium (1 g/day) and vitamin D (at least 1000 IU/day) and monitoring of bone status may be suggested to minimize osteopenia. Care must be taken to avoid serum calcium levels greater than 11 mg/dL and 25-OH vitamin D levels less than 35 ng/mL. Edema often occurs and may require diet modification, including a sodium- and fluid-restricted diet. Other side effects of steroid use include cushingoid syndrome and gastrointestinal bleeding.

## UNCONFIRMED THERAPIES

Because modern medicine cannot promise a cure or even permanent relief of symptoms, many persons turn to alternative approaches for help. With growing access to the Internet, patients have a greater exposure to remedies and controversial treatments. In a recent survey, rheumatologists in the United States showed a widespread favorable opinion toward many alternative therapies for patients with rheumatic diseases (Manek et al., 2010).

Favorable effects of self-help treatments are often reported anecdotally, but as a rule no cause-and-effect relationships are documented. Any amelioration can usually be attributed to the placebo effect or to characteristic cycles of worsening followed by periods of improvement. Therapies that are scientifically proven safe and effective can be promoted, whereas caution is needed in regard to therapies for which the science is limited.

Some remedies have their roots in medicine. Salicylates in aspirin are derived from willow bark; they have been around as a medicinal remedy for pain and inflammation for centuries. Willow bark and ginger may relieve pain because their chemical composition is similar to NSAIDs, but excessive blood thinning is a concern (Marcus, 2005). Additional research is needed on valerian, feverfew, boswellia, and curcumin before recommendations can be made for

their usefulness in treating RA (National Center for Complementary and Alternative Medicine [NCCAM], 2009).

Although much of the dietary experimentation is harmless except for the costs, some self-treatment modalities can be harmful. It is best to avoid copper or copper salts, shark cartilage, devil's claw, echinacea, guaifenesin, alfalfa, wild

yam, and methylsulfonylmethane (MSM). Both comfrey and alfalfa are herbs that have been promoted as potential cures for arthritis, yet both have been deemed toxic by the scientific community. Meditation, tai chi, relaxation techniques, thermotherapy and spiritual practice may offer pain reduction. Biofeedback, relaxation, chlorella supplements, magnet

therapies, homeopathy, botanical oils, and dietary modifications need further study before general recommendations can be made.

## OSTEOARTHRITIS

**Osteoarthritis (OA)**, formally known as *degenerative arthritis* or *degenerative joint disease*, is the most prevalent form of arthritis. Obesity, aging, female gender, white ethnicity, greater bone density, and repetitive-use injury associated with athletics have been identified as risk factors. OA is not systemic or autoimmune in origin, but involves cartilage destruction with asymmetric inflammation. It is caused by joint overuse, whereas RA is a systemic autoimmune disorder that results in symmetric joint inflammation.

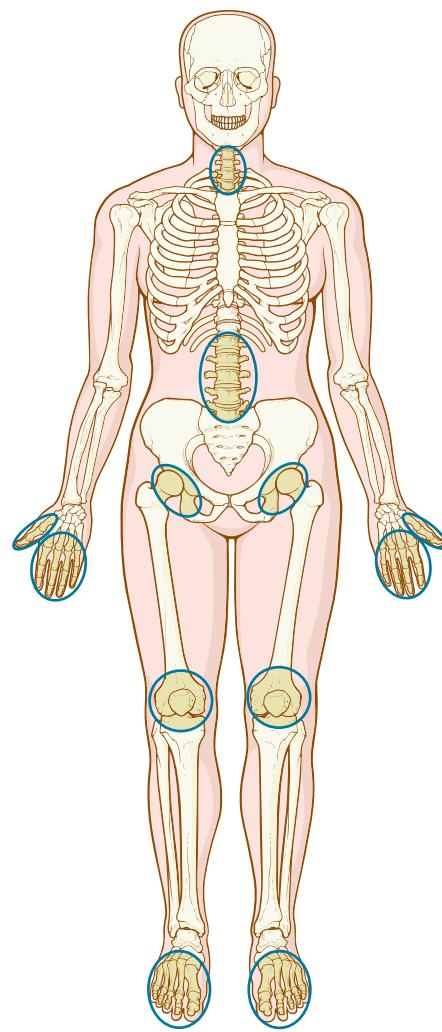

### Pathophysiology

OA is a chronic joint disease that involves the loss of habitually weight-bearing articular (joint) cartilage. This cartilage normally allows bones to glide smoothly over one another. The loss can result in stiffness, pain, swelling, loss of motion, and changes in joint shape, in addition to abnormal bone growth, which can result in osteophytes (bone spurs) (Huskisson, 2008) (see Figure 40-1 and the *Pathophysiology and Care Management Algorithm: Osteoarthritis*).

The joints most often affected in OA are the distal interphalangeal joints, the thumb joint, and, in particular, the joints of the knees, hips, ankles, and spine, which bear the bulk of the body's weight (Figure 40-2). The elbows, wrists, and ankles are less often affected. OA generally presents as pain that worsens with weight bearing and activity and improves with rest, and patients often report morning stiffness or "gelling" of the affected joint after periods of inactivity. Diseases of the joints influenced by congenital and mechanical derangements may contribute to OA as well. Inflammation occurs at times but is generally mild and localized.

### Medical and Surgical Management

The patient's medical history and level of pain should determine the most appropriate treatment. This should include

**FIGURE 40-2** Joints commonly affected by osteoarthritis.

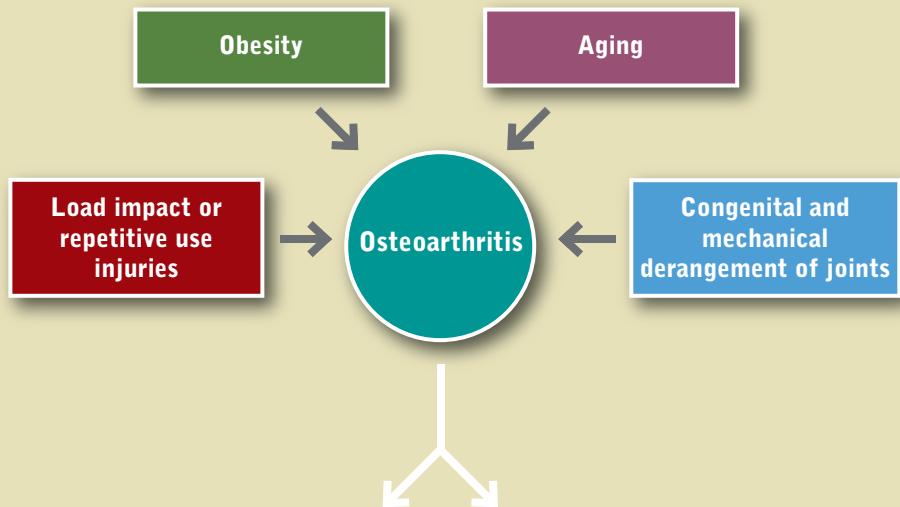

nonpharmacologic modalities (patient education, physical and occupational therapy), pharmacologic agents, and surgical procedures with the goals of pain control, improved function and health-related quality of life, and avoidance of toxic effects from treatment (Huskisson, 2010). Weight loss and/or achievement of ideal body weight (body mass index

## PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

### Osteoarthritis

ETIOLOGY

PATHOPHYSIOLOGY

#### Clinical Findings

- Breakdown of articular cartilage
- Changes in joint shape
- Osteophytes/bone spurs
- Cartilage or bone fragments in synovial fluid

#### Joint Symptoms

- Stiffness
- Pain
- Swelling
- Loss of motion
- Crunching feeling of bone on bone

MANAGEMENT

#### Medical Management

- Drug Therapy:** NSAIDs, corticosteroids, topical and other pain relievers  
**Health Behavior Changes:** Exercise, weight control, rest and relief from stress on joints  
**Non-Drug Pain Relief:** Heat and cold, TENS, massage

#### Nutrition Management

- Balanced diet with appropriate kcal for weight loss or maintenance of appropriate weight
- Anti-inflammatory diet
- ω-3 fat supplementation
- Adequate calcium and vitamin D
- Consideration of glucosamine and chondroitin

[BMI] of 18.5-24.9) should be part of the medical treatment as it improves OA dramatically. See Chapter 22.

Patients with severe symptomatic OA pain who have not responded adequately to medical treatment and who have been progressively limited in their **activities of daily living (ADLs)**, such as walking, bathing, dressing, and toileting, should be evaluated by an orthopedic surgeon. Surgical options include arthroscopic debridement (with or without

arthroplasty), total joint arthroplasty, and osteotomy. Surgical reconstruction has been quite successful but should not be viewed as a replacement for overall good nutrition, maintenance of healthy body weight, and exercise.

#### Exercise

OA limits the ability to increase energy expenditure through exercise. It is critical that the exercise be done with correct

form so as not to cause damage or exacerbate an existing problem. Physical and occupational therapists can provide unique expertise for OA patients by making individualized assessments and recommending appropriate exercise programs and assistive devices, in addition to offering guidance regarding joint protection and energy conservation. Non-loading aerobic (swimming), range-of-motion, and weight-bearing exercises have all been shown to reduce symptoms, increase mobility, and lessen continuing damage from OA. Nonweight-bearing exercise may also serve as an adjunct to NSAID use (Egan and Mentes, 2010).

Sports or strenuous activities that subject joints to repetitive high impact and loading increase the risk of joint cartilage degeneration. Therefore increased muscle tone and strength, correct form, general flexibility, and conditioning will help protect these joints in the habitual exerciser. A walking program and lower-extremity strength training are beneficial for individuals with knee OA (Zhang et al., 2008).

## Medical Nutrition Therapy

### Weight and Adiposity Management

Excess weight puts an added burden on the weight-bearing joints. Epidemiologic studies have shown that obesity and injury are the two greatest risk factors for OA. The risk for knee OA increases as the BMI increases. Controlling obesity can reduce the burden of OA through both disease prevention and improvement in symptoms (Holliday et al., 2010). A well-balanced diet that is consistent with established dietary guidelines and promotes attainment and maintenance of a desirable body weight is an important part of MNT for OA.

### Anti-Inflammatory Diet

Recently, the **anti-inflammatory diet**, a diet resembling the Mediterranean diet, has been useful (Marcason, 2010) (Box 40-2). The diet aims for variety, the inclusion of as much fresh food as possible, the least amount of processed foods and fast food, and an abundance of fruits and vegetables. When combined with moderate exercise, diet-induced weight loss has been shown to be an effective intervention for knee OA (Egan and Mentes, 2010). There is also an anti-inflammatory effect from weight loss in OA management because the reduced fat mass results in the presence of less inflammatory mediators from adipose tissue (see Chapter 22).

### Vitamins and Minerals

Cumulative damage to tissues mediated by reactive oxygen species has been implicated as a pathway that leads to many of the degenerative changes seen with aging. However, large doses of dietary antioxidants, including vitamin C, the tocopherols (vitamin E), β-carotene, and selenium have shown no benefit for the management of symptomatic OA (Canter et al., 2007; Rosenbaum et al., 2010).

Many patients with OA consume deficient levels of calcium, and vitamin D. Low serum levels of vitamin D are being studied for their role in OA progression (McAlindon

### BOX 40-2

#### The Anti-inflammatory Diet

- General principles:** Aims for variety, with plenty of fresh food, the least amount of processed foods and “fast foods,” and abundant fruits and vegetables.
  - Includes plenty of fruits and vegetables, except onions and potatoes, which contain the alkaloid solanine.
  - Low in saturated fat and devoid of trans fats.
  - Low in ω-6 fats, such as vegetable oils and animal fat.
  - High in ω-3 PUFAs such as those found in olive oil, flax, walnuts, pumpkin seeds and fatty cold-water oily fish like salmon, sardines, mackerel, and herring. Other healthy oils include grapeseed, walnut, and canola.
  - Low in refined carbohydrates such as sucrose, pasta, white bread, and white rice.
  - Favors intake of whole grains such as brown rice and bulgur wheat.
  - Includes lean protein sources such as chicken and fish.
  - Low in eggs, red meat, butter, and other full-fat dairy products
  - Low in refined and processed foods.
  - Includes spices such as ginger, curry, turmeric, and rosemary, which are claimed to have anti-inflammatory effects.
  - Includes good sources of phytonutrients: fruits and vegetables of all colors, especially berries, tomatoes, orange and yellow fruits, and dark leafy greens; cruciferous vegetables (cabbage, broccoli, brussels sprouts); soy foods, tea (especially white, green or oolong), dark plain chocolate in moderation.
  - Additionally, weight should be maintained within healthy parameters, and exercise should be included.
- Data from Sears B: Anti-inflammatory diets for obesity and diabetes, J Am Coll Nutr 28:482S, 2009; Web MD: Anti-inflammatory diet: road to good health? Accessed from [www.webmd.com/diet/guide/anti-inflammatory-diet-road-to-good-health](http://www.webmd.com/diet/guide/anti-inflammatory-diet-road-to-good-health).
- PUFA, Polyunsaturated fatty acid.

and Biggee, 2005). Improving intake to at least dietary reference intake (DRI) levels is important. Comprehensive nutrition interviewing and counseling should include a determination of acceptable sources of all nutrients for the OA patient, as well as supplementation of the diet to achieve the recommended levels with special attention given to vitamin B<sub>6</sub>, vitamin D, vitamin K, folate, and magnesium.

### Alternative Therapies

A variety of alternative therapies have been proposed to manage pain in OA, including topical aids, manipulative therapies, and acupuncture. **Capsaicinoids**, derived from chili peppers, have a fatty acid receptor that stimulates, then blocks, small-diameter pain fibers by depleting them of the neurotransmitter substance P, thought to be the principal chemomediator of pain impulses from the periphery. Capsaicin, applied with glyceryl trinitrate to reduce onsite

burning, can reduce pain in OA patients (Kosuwon, 2010). Certain pulsed electromagnetic fields can also affect the growth of bone and cartilage with potential use in OA, and use of static magnets may provide temporary pain relief under certain circumstances (Pittler et al., 2007).

According to the Arthritis Foundation (AF), S-adenosyl-L-methionine (SAM-e) has also shown promise for reducing pain and improving mobility in people with OA at doses of 600 to 1200 mg/day, but should not be taken without a doctor's supervision (Arthritis Foundation [AF], 2007). A systematic review and meta-analysis also found benefit for OA patients treated with acupuncture (Kwon et al., 2006).

Other alternative therapies used to help lessen the need for medication are glucosamine sulfate, chondroitin sulfate, oils, and herbs. Other modalities include diacerein, avocado soybean unsaponifiables, and hyaluronic acid that have a symptomatic effect and low toxicity, but overall effects are small (Zhang et al., 2007). Advocates of these alternative modalities cite reports of progressive and gradual decline of joint pain and tenderness, improved mobility, sustained improvement after drug withdrawal, and a lack of toxicity associated with short-term use of these agents (AF, 2005a).

### Glucosamine and Chondroitin

Sodium chondroitin sulfate (chondroitin sulfate) and glucosamine hydrochloride (glucosamine) are both involved in cartilage production, but their mechanism for eliminating pain has not been identified. Limited data suggest that glucosamine sulfate administered orally, intravenously, intramuscularly, or intraarticularly may produce a gradual and progressive reduction in joint pain and tenderness, as well as improved range of motion and walking speed (Huskinson, 2008). Glucosamine has produced consistent benefits, including greater than 50% improvement in symptom scores in patients with OA. In some cases glucosamine may be equal or superior to ibuprofen (McAlindon and Biggee, 2005). Together glucosamine and chondroitin rank third among all top-selling nutritional products in the United States.

The National Institutes of Health (NIH) undertook the Glucosamine/Chondroitin Arthritis Intervention Trial (GAIT), the first, large-scale, multicenter clinical trial in the United States to test the effects of these supplements on knee OA. A dose of 1500 mg of glucosamine (500 mg, three times daily) with 1200 mg of chondroitin (400 mg, three times daily) resulted in statistically significant pain relief for a small subset of participants who had moderate to severe pain, but not for those in the mild pain subset. Compared with 54% of those taking placebo, 79% of those taking glucosamine and chondroitin reported a 20% or greater reduction in pain. Because of the small sample size, these findings are considered preliminary (National Institutes of Health [NIH], 2008). Although it is not effective for all afflicted individuals, a safe dose of glucosamine and chondroitin sulfate is 1500 mg/day and 1200 mg/day in divided doses, respectively (AF, 2005a). GAIT and other studies have found no change in glucose tolerance (NIH, 2006). A

metaanalysis report that looked at more than 3000 human subjects found no adverse effects of oral glucosamine administration on blood, urine, or fecal parameters and no serious or fatal side effects (Anderson et al., 2005). In contrast, chondroitin is chemically similar to commonly used blood thinners and could cause excessive bleeding if used in combination with blood thinners. Chondroitin may also elicit a reaction in those with shellfish allergies.

## RHEUMATOID ARTHRITIS

**Rheumatoid arthritis (RA)** is a debilitating and frequently crippling autoimmune disease with overwhelming personal, social, and economic effects. Although less common than OA, RA is usually more severe. RA affects the interstitial tissues, blood vessels, cartilage, bone, tendons, and ligaments, as well as the synovial membranes that line joint surfaces. RA occurs more frequently in women than in men. The peak onset commonly occurs between 20 and 45 years of age.

Numerous remissions and exacerbations generally follow its onset, although for some people it lasts just a few months or years and then goes away completely. Although any joint may be affected by RA, involvement of the small joints of the extremities—typically the proximal interphalangeal joints of the hands and feet—is most common (Figure 40-3).

### Pathophysiology

RA is a chronic, autoimmune, systemic disorder in which **cytokines** and the inflammatory process play a role. RA has articular manifestations that involve chronic inflammation that begins in the synovial membrane and progresses to subsequent damage in the joint cartilage (*Pathophysiology and Care Management Algorithm: Rheumatoid Arthritis*). Although the exact cause of RA is still unknown, certain genes have been discovered that play a role. The likely trigger is a viral or bacterial infection. It has been suggested

**FIGURE 40-3** A patient with advanced rheumatoid arthritis. The twisted hands and the puffiness of the metacarpal joints are typical of the disease. (From Damjanov I: *Pathology for the health-related professions*, ed 3, Philadelphia, 2006, Saunders.)

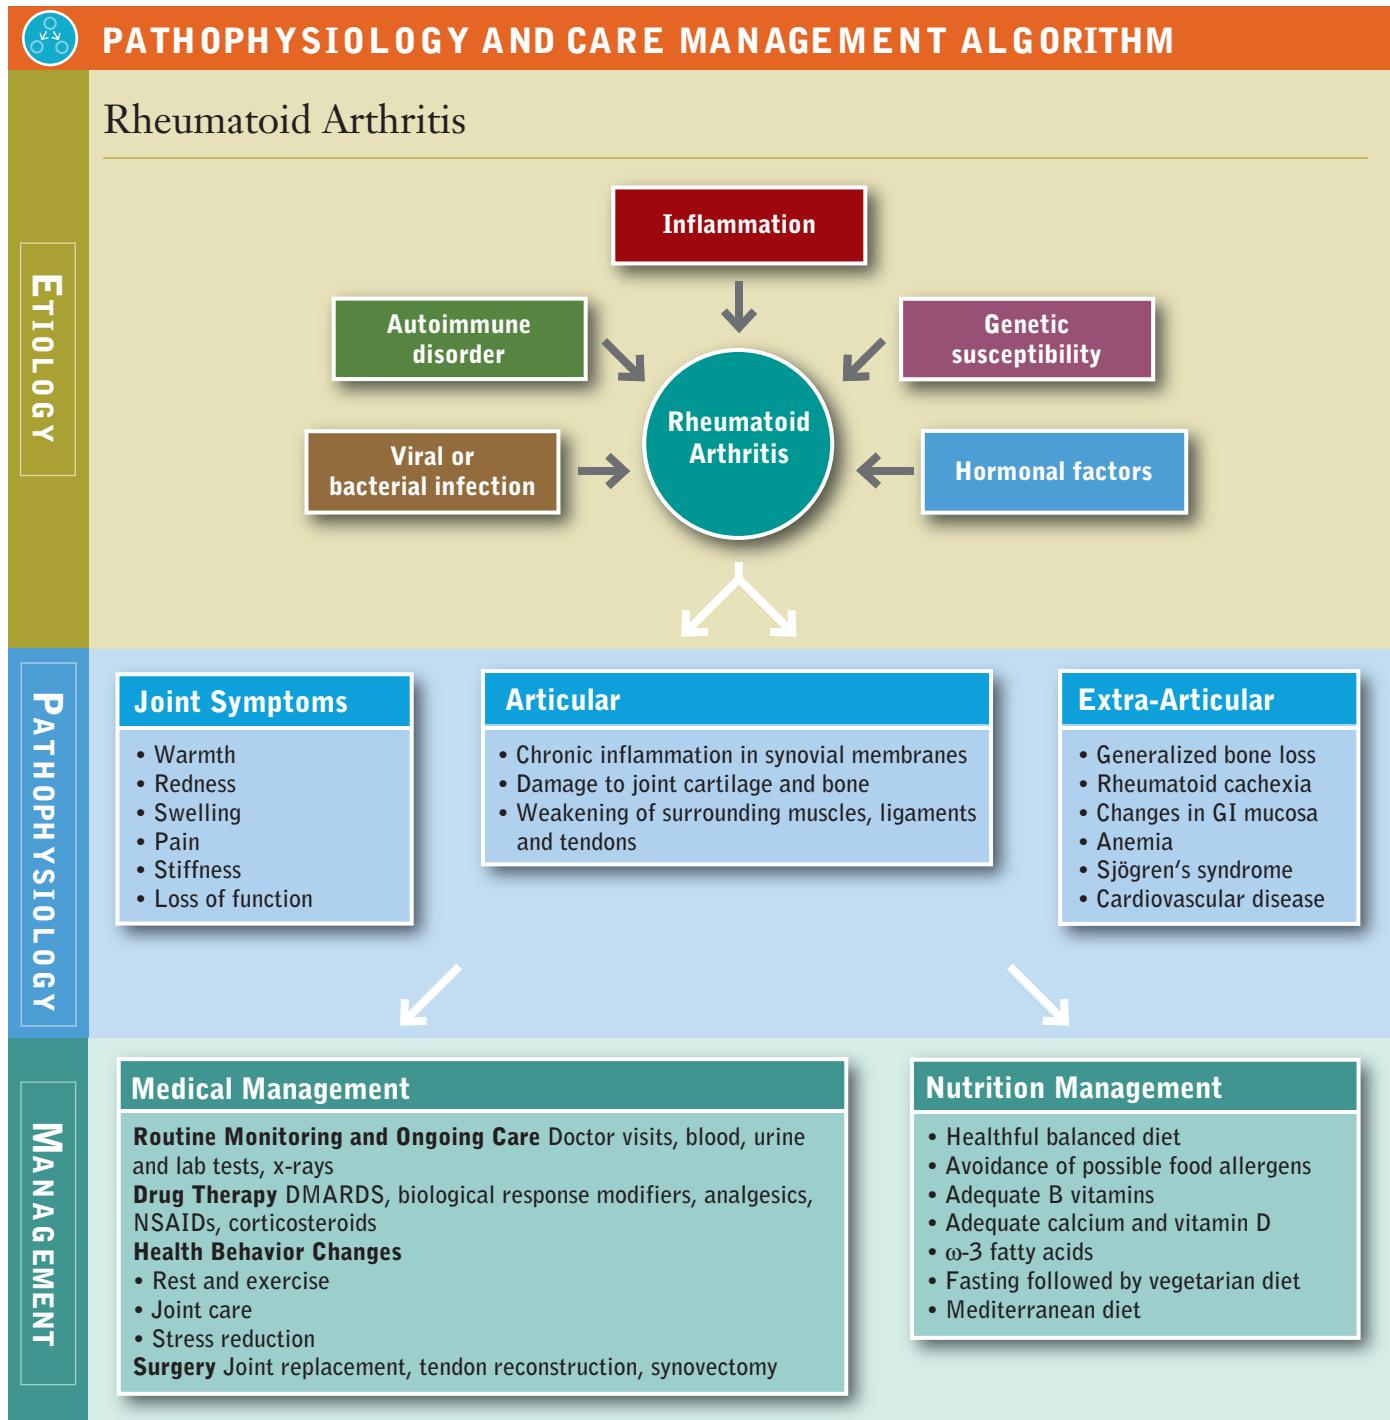

that drinking large amounts of tea may increase the risk of developing RA (Walitt et al, 2010); however, other studies have suggested that teas are protective. More research is clearly needed.

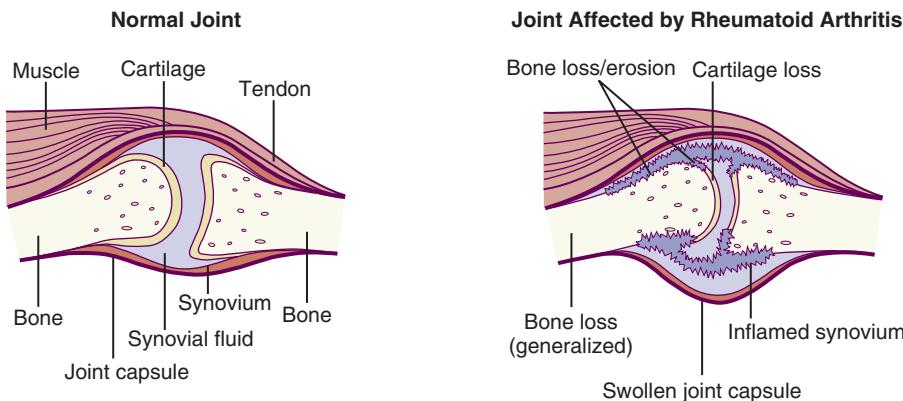

## Medical Management

The appearance of rheumatoid factor (RF), may precede symptoms of RA. Pain, stiffness, swelling, loss of function,

and anemia are common. The swelling or puffiness is caused by the accumulation of synovial fluid in the membrane lining the joints and inflammation of the surrounding tissues (Figure 40-4).

RA patients are at increased risk for cardiovascular disease, explained by the systemic inflammatory response (Snow and Mikuls, 2005). This is especially significant considering findings regarding COX-2 selective NSAIDs. In

**FIGURE 40-4** Comparison of a normal joint and one affected by rheumatoid arthritis, which has swelling of the synovium. (From National Institute of Arthritis and Musculoskeletal and Skin Diseases: Handout on health: rheumatoid arthritis, NIH Publication Number 04-4179, January 1998, Revised May 2004. National Institutes of Health, Department of Health and Human Services.)

fact, many of the drugs used to treat RA can result in hyperhomocysteinemia, hypertension, and hyperglycemia, all risk factors for cardiovascular disease. Conveniently, treatment aimed at reducing inflammation may benefit both diseases (Snow and Mikuls, 2005).

### Pharmacologic Therapy

Medications to control pain and inflammation are the mainstay of treatment for RA. Salicylates and NSAIDs are often the first line of treatment, and methotrexate (MTX) is commonly prescribed as well, but these drugs may cause significant side effects. The choice of drug class and type is based on patient response to the medication, incidence and severity of adverse reactions, and patient compliance. Drug-nutrient side effects can occur with any of the drugs. Side effects of drug use may influence ingestion, digestion, and absorption, and hence nutrition status. See Chapter 9 and Appendix 31.

Salicylates are commonly used. However, chronic aspirin ingestion is associated with gastric mucosal injury and bleeding, increased bleeding time, and increased urinary excretion of vitamin C. Taking aspirin with milk, food, or an antacid often alleviates the gastrointestinal symptoms. Vitamin C supplementation is prescribed when serum levels of ascorbic acid are abnormally low. See Appendix 30.

**Disease-modifying antirheumatic drugs (DMARDs)** may be prescribed because of their unique ability to slow or prevent further joint damage caused by arthritis. These include MTX, sulfasalazine (Azulfidine), hydroxychloroquine (Plaquenil), azathioprine (Imuran), and leflunomide (Arava). In fact, the ACR recommends that the majority of patients with newly diagnosed RA be prescribed a DMARD within 3 months of diagnosis. Depending on which drug is selected, side effects can include myelosuppression or macular or liver damage. A main adverse effect of the DMARD MTX treatment is folate antagonism. Treatment with MTX induces a significant rise in serum homocysteine, which is corrected by folic acid supplementation and a properly balanced diet. Supplementation is advised to offset the toxicity of this drug, for protection against gastrointestinal disturbances, and for maintenance of red blood cell

production without reducing the efficacy of MTX therapy. Long-term supplementation in patients on MTX is important to prevent neutropenia, mouth ulcers, nausea, and vomiting (see Appendix 31 and Chapters 9 and 31).

D-penicillamine is another DMARD, which acts as immunosuppressor by reducing the number of T cells, inhibiting macrophage function and decreasing IL-1 and RF production. Additional DMARDs include gold salt therapy and antimalarials and may lead to a remission in RA symptoms. Proteinuria may occur with administration of gold and D-penicillamine; therefore toxicity must be monitored continually. Minocycline (Minocin) is an antibiotic often used to treat mild RA (Cannon, 2009).

### Surgery

Surgical treatment for RA may be considered if pharmacologic and nonpharmacologic treatment cannot adequately control the pain or maintain acceptable levels of functioning. Common surgical options include synovectomy, joint replacement, and tendon reconstruction.

### Exercise

Physical and occupational therapy are often part of the initial therapy for newly diagnosed RA, but may also be integrated into the treatment plan as the disease progresses and ADLs are affected. To maintain joint function, recommendations may be given for energy conservation, along with range-of-motion and strengthening exercises. Although the patient may be reluctant at first, individuals with RA can participate in conditioning exercise programs without increasing fatigue or joint symptoms while improving joint mobility, muscle strength, aerobic fitness, and psychological well-being.

A loss of body cell mass that accompanies RA, called **rheumatoid cachexia**, involves the skeletal muscle, viscera, and immune system. This can lead to muscle weakness and loss of function, which may hasten morbidity and mortality in RA. Physical activity, including both aerobic exercise and strength training, seems to help. Any exercise program for an RA patient must take into account the individual's disease status.

## Medical Nutrition Therapy

The nutrition care process and model serves as a guide for implementing MNT with RA patients. See Chapter 11. A comprehensive nutrition assessment of individuals with RA is essential, with a review of systems to determine the systemic effects of the disease process. A physical examination provides diagnostic signs and symptoms of nutrient deficiencies. Current weight and history of weight change over time are the least expensive, least invasive, and most reliable assessment tools to use. Weight change is an important measure of RA severity. The characteristic progression of malnutrition in RA is attributed to excessive protein catabolism evoked by inflammatory cytokines and by disuse atrophy resulting from functional impairment (Fukuda et al., 2005).

The diet history should review the usual diet; the effect of the handicap; types of food consumed; and changes in food tolerance secondary to oral, esophageal, and intestinal disorders. The effect of the disease on food shopping and preparation, self-feeding ability, appetite, and intake also needs to be assessed. The use of elimination or other diets purported to treat or cure arthritis should be identified (Smedslund, 2010). See Chapters 4, 6, and 8.

Articular and extraarticular manifestations of RA affect the nutrition status of individuals in several ways. Articular involvement of the small and large joints may limit the ability to perform nutrition-related ADLs, including shopping for, preparing, and eating food. Involvement of the temporomandibular joint can affect the ability to chew and swallow and may necessitate changes in diet consistency. Extraarticular manifestations include increased metabolic rate secondary to the inflammatory process, SS, and changes in the gastrointestinal mucosa.

Increased metabolic rate secondary to the inflammatory process leads to increased nutrient needs, often in the face of a diminishing nutrient intake. Taste alterations secondary to xerostomia and dryness of the nasal mucosa; dysphagia secondary to pharyngeal and esophageal dryness; and anorexia secondary to medications, fatigue, and pain may reduce dietary intake. Changes in the gastrointestinal mucosa affect intake, digestion, and absorption. The effect of RA and the medications used may be evident throughout the gastrointestinal tract. Based on the patient's unique profile, a registered dietitian can determine the most appropriate nutrition intervention, followed by monitoring and evaluation.

The association of foods with disease flares should be discussed. Whether food intake can modify the course of RA is an issue of continued scientific debate and interest. Dietary manipulation by either modifying food composition or reducing body weight may give some clinical benefit in improving RA symptoms. Some benefits may be related to a reduction in immunoreactivity to food antigens eliminated by a change in diet (Karatay et al., 2005) (see Chapter 27).

Some literature has suggested that fasting may be beneficial in reducing pain at the inflammation site; nevertheless fasting has never been shown as an effective treatment for RA symptoms (Smedslund et al., 2010). A vegan, gluten-free

diet causes improvement in some patients, possibly because of the reduction of immunoreactivity to food antigens. See Chapter 27.

The anti-inflammatory diet described in Box 40-2 should be considered. The similar Mediterranean-style eating plan includes foods that almost everyone should aim to consume on a daily basis, such as moderate amounts of lean meat, unsaturated fats instead of saturated fats, plenty of fruits and vegetables, and fish. See Fig. 34-6. These diets are also nutritionally adequate and cover all of the food groups (Smedslund et al., 2010).

If food does play a role in RA, it most likely does so a few years before clinical diagnosis (Pedersen et al., 2005). Red meat has been identified as having proinflammatory properties as a source of ARA (see Box 40-1); no link has been identified between RA and coffee or tea consumption (Choi and Curhan, 2010).

## Energy

Objective measures of actual energy needs for this population have not been determined. It is important to remember that the actual effect of the inflammatory response on the metabolic rate is unknown and may vary from individual to individual. In addition, activity levels vary greatly. Although traditional measures to assess energy requirements can be used, weight should be monitored and energy intake modified as needed to achieve desirable or usual body weight. Methods to determine energy requirements are noted in Chapter 2. For patients who are totally sedentary, calculations should be estimated at the resting energy expenditure and adjusted for weight changes that occur over time. When intakes are poor, enteral or parenteral supplementation may be required, and home nutrition support is beneficial for chronic cases. See Chapter 14.

## Protein

Well-nourished individuals require protein at levels comparable to the DRIs for age and sex. Patients with RA tend to have increased whole-body protein breakdown (regardless of age) from growth hormone factor, glucagon, and TNF- $\alpha$  production. Protein may be needed at levels of 1.5 to 2 g/kg/day.

## Lipids

Low-fat diets (including use of low-fat substitutes) lead to low serum levels of vitamins A and E and actually stimulate lipid peroxidation and eicosanoid production, thus aggravating RA. Therefore low-fat or fat-free dieting may actually be counterproductive for patients susceptible to or afflicted by RA. Rather than eliminating fat, changing the type of fat in the diet is useful and likely offers advantages for both the arthritis and cardiovascular systems. The anti-inflammatory diet (Box 40-2) with higher  $\omega$ -3 fatty acids can reduce inflammatory activity, increase physical function, and improve vitality for RA patients.

Omega-3 fatty acids have increased in popularity in the management of RA because of their role in inflammatory pathways. Some other oils of marine origin and a range of

vegetable oils (olive and evening primrose oil) have indirect antiinflammatory actions probably mediated via PG E<sub>1</sub> (see *Focus On: Fatty Acids and the Inflammatory Process*). Fish oil alleviates RA symptoms and reduces the use of NSAIDS in RA patients. The beneficial effects are generally delayed for up to 12 weeks after they are started but last up to 6 weeks after discontinuing therapy (Bhangle and Kolasinski, 2011). See Appendix 40 for ω-3 and ω-6 fatty acid content of foods.

### Minerals, Vitamins, and Antioxidants

Several vitamins and minerals function as antioxidants and therefore affect inflammation. Vitamin E is just such a vitamin, and along with ω-3 and ω-6 fatty acids, may affect cytokine and eicosanoid production by decreasing proinflammatory cytokines and lipid mediators. Synovial fluid and plasma trace element concentrations, excluding Zn, change in inflammatory RA. Altered trace element concentrations in inflammatory RA may result from changes of the

immunoregulatory cytokines (Yazar et al., 2005). Degradation of collagen and eicosanoid stimulation are associated with oxidative damage. However, there are not significant data to support routine supplementation with vitamin C, vitamin A, or β-carotene unless patients are shown to have inadequate concentrations of antioxidants.

RA patients often have nutritional intakes below the DRIs for folic acid, calcium, vitamin D, vitamin E, zinc, vitamin B, and selenium. In addition the often used drug MTX is known to decrease serum folate levels with the result of elevated homocysteine levels. Thus in these patients, adequate intakes of folate and vitamins B<sub>6</sub> and B<sub>12</sub> should be encouraged. Calcium and vitamin D malabsorption and bone demineralization are characteristic of advanced stages of the disease, leading to osteoporosis or fractures. Prolonged use of glucocorticoids can also lead to osteoporosis. Therefore supplementation with calcium and vitamin D should be considered. Indeed, vitamin D is a

### © FOCUS ON

## Fatty Acids and the Inflammatory Process

Two classes of polyunsaturated fatty acids—ω-6 and ω-3—are metabolized competitively, including conversion to their corresponding eicosanoids: prostanoids (prostaglandin [PG] and thromboxane [Tx]) and leukotrienes (LTs). Eicosapentaenoic acid (EPA, 20:5) and docosahexaenoic acid (DHA, 22:6) are ω-3 polyunsaturated fatty acids (PUFAs) that are abundant in cold-water fish such as salmon, sardines, mackerel, herring, tuna, fish oils and some algae. α-Linolenic acid (ALA, 18:3) is also an ω-3 PUFA found in abundance in flaxseed, walnuts, and soy and canola (rapeseed) oils. EPA, DHA, and ALA have all been shown to replace the synthesis of inflammatory eicosanoids by competing with the conversion of arachidonic acid (ARA, 20:4 ω-6) to the series 2 of PG and Tx. ARA comes exclusively from animal foods. Linoleic acid (LA, 18:2), an ω-6 PUFA found in safflower and other oils, is a precursor of ARA; therefore its consumption should be limited in rheumatic patients.

The type of mediator that is produced is determined by the type of PUFAs present in the phospholipids of the cell membrane, which in turn is influenced by the type of PUFAs in the diet. Theoretically, a person can replace ω-6 PUFAs with ω-3 PUFAs by increasing their consumption. This in turn, will result in the synthesis of prostanoids (PG and Tx) with antiinflammatory effects. Similarly, reducing the amount of ARA minimizes inflammation and can enhance the benefits of fish oil supplementation.

Studies during the last 20 years have clearly shown beneficial changes in eicosanoid metabolism with fish oil supplementation in patients with rheumatoid arthritis (Calder et al., 2009; Galli et al., 2009), even when administered parenterally (Bahadori et al., 2010). Although fish oil seems to exert an

antiinflammatory effect in short-term studies, these effects may vanish during long-term treatment because of decreased numbers of autoreactive T cells via apoptosis. In already existing disease increased consumption might not be beneficial. (Calder et al., 2009).

Lowered intake of ω-6 fatty acids and increased intake of ω-3 oils should not replace conventional drug therapies. These oils should be used in conjunction with improved eating habits. A diet that includes baked or broiled fish one to two times per week, or an ω-3 supplement (approximate daily dose up to: EPA-50 mg/kg/day, DHA-30 mg/kg/day) can be recommended for rheumatoid arthritis patients. However, the Food and Drug Administration (FDA) has identified shark, swordfish, king mackerel, and tilefish as high-mercury fish that should be avoided. Although the quality of fish oil supplements is steadily improving, these supplements are not without their own side effects, such as their fishy taste or odor, causing increased bleeding time or gastrointestinal distress; although these manifestations are usually dose dependent (Bhangle and Kolasinski, 2011).

Additional benefits may come from a combination of fish oils and olive oil (Berbert et al., 2005). A component of olive oil has been shown to inhibit cyclooxygenase enzyme in the synthesis of prostaglandins just as ibuprofen can. This action has been attributed to oleocanthal, a compound in newly pressed extra virgin olive oil that has natural antiinflammatory activity (Beauchamp et al., 2005). More studies are needed to determine an effective dose and identify any limits to its use for patients with rheumatic disease. The addition of an antioxidant is required to improve the oxidative stability of olive oil (Lee et al., 2006).

selective immunosuppressant and greater intakes of vitamin D may be beneficial. Because of drug-induced alterations in specific vitamin or mineral levels, mounting evidence supports supplementation beyond the minimum levels for vitamins D and E, folic acid and vitamins B<sub>6</sub> and B<sub>12</sub>.

Elevated levels of copper and ceruloplasmin in serum and joint fluid are seen in RA. Plasma copper levels correlate with the degree of joint inflammation, decreasing as the inflammation is diminished. Elevated plasma levels of ceruloplasmin, the carrier protein for copper, may have a protective role because of its antioxidant activity.

### Alternative Therapies

The increasing popularity of the use of alternative treatments appears to be particularly evident with people afflicted with RA. Herbal therapy is popular; however, concerns of toxicity must also be addressed because the Food and Drug Administration (FDA) provides relatively little regulation of herbal therapies.

Gamma-linolenic acid (GLA) is an ω-6 fatty acid found in the oils of black currant, borage, and evening primrose that can be converted into the antiinflammatory PG E<sub>1</sub> or into ARA, a precursor of the inflammatory PG E<sub>2</sub>. Because of competition between ω-3 and ω-6 fatty acids for the same enzymes, the relative dietary contribution of these fats appears to affect which pathways are favored. The enzyme delta-5 desaturase converts GLA into ARA, but a diet high in ω-3 fats will pull more of this enzyme to the ω-3 pathway, allowing the body to use GLA to produce PGE<sub>1</sub>. This anti-inflammatory PGE<sub>1</sub> may relieve pain, morning stiffness, and joint tenderness with no serious side effects. Further studies are required to establish optimum dosage and duration.

Thunder god vine (*Tripterygium wilfordii*) has been used in China to treat patients with a number of autoimmune diseases. There are no consistent, high-quality thunder god vine preparations being manufactured in the United States. High doses and long-term use of thunder god vine may suppress the immune system and reduce bone density (NCCAM, 2009).

## SJÖGREN'S SYNDROME

**Sjögren's syndrome (SS)** is a chronic autoimmune disease characterized by lymphocytic infiltration of the exocrine glands, particularly the salivary and lacrimal glands, leading to dryness of the mouth (xerostomia) and of the eyes (xerophthalmia).

### Pathophysiology

Common signs include thirst, burning sensation in the oral mucosa, inflammation of the tongue (glossitis), and lips (cheilitis), cracking of the corners of the lips (cheilosis), difficulties in chewing and swallowing (dysphagia), severe dental caries, progressive dental decay, and nocturnal oral discomfort. SS can be present alone (primary SS) or as secondary SS, as a result of another rheumatic disorder (RA, lupus). Patients may also suffer from disorders of the skin,

lung, kidney, nerve, connective tissue, and digestive system because of more extensive glandular damage.

SS patients frequently develop disturbances in smell perception (dysosmia) and in taste acuity (dysgeusia) (Gomez et al., 2004; Kamel et al., 2009), as well as in their dietary habits because of difficulties in biting, chewing, or swallowing.

Nutrient insufficiency may play a role in the development or progression of SS. Altered consumption of several nutrients has been noted in SS patients including higher intake of supplemental calcium and lower intake of nonsupplemental vitamin C, PUFAs, linoleic acid, and ω-3 fatty acids. Biochemical deficiency of vitamin B<sub>6</sub> (pyridoxine) has also been observed (Tovar et al., 2002). That can be corrected by pyridoxine supplementation.

### Medical Management

Medications for SS address the issues of dry eyes and dry mouth. These include artificial tears and immunosuppressive drops such as cevimeline (Evoxac) and pilocarpine (Salagen), respectively (AF, 2005b).

### Medical Nutrition Therapy

The goal of dietary management in patients with SS is to relieve symptoms and reduce eating discomfort, which can result in lack of appetite, weight loss, fatigue, difficulty chewing and swallowing, mouth infections, and anemia. Management of xerostomia should also include strategies for reducing the risk of dental decay, including frequent rinsing with water, toothbrushing, using topical fluorides, or chewing sugar-free gum. Because of the lack of saliva (and the protective substances normally present in it), sugary foods should be reduced or eliminated from the diet to minimize cavities. If sugary foods or beverages are consumed, the teeth should be brushed and rinsed with water immediately.

Because swallowing is a problem, ready-to-eat foods may be useful. Foods should all be moist, and extremes in temperature should be avoided. The most common modifications include soaking or overcooking certain foods to make them softer; chopping and cutting meats and fruits to make them smaller; and limiting consumption of citrus fruits, irritant foods, and spices. The tartness of artificially sweetened, sour-flavored hard candy may help to stimulate salivary flow. Artificial saliva or products such as lemon glycerin may also be recommended by dental or dietetic professionals.

Malnutrition does not seem to be more common in this population. Iron and vitamin deficiencies such as vitamin C, vitamin B<sub>12</sub>, vitamin B<sub>6</sub> and folate are possible, but these can be easily avoided with a well-balanced diet or appropriate vitamin supplementation.

## TEMPOROMANDIBULAR DISORDERS

**Temporomandibular disorders (TMDs)** affect the temporomandibular joint, which connects the lower jaw (mandible)

to the temporal bone. TMDs can be classified as myofascial pain, internal derangement of the joint, or degenerative joint disease. One or more of these conditions may be present at the same time, causing pain or discomfort in the muscles or joint that control jaw function.

### Pathophysiology

Besides experiencing a severe jaw injury, there is little scientific evidence to suggest a cause for TMD. It is generally agreed that physical or mental stress may aggravate this condition.

### Medical Nutrition Therapy

The goal of dietary management is to alter food consistency to reduce pain while chewing. According to the National Institute of Dental and Craniofacial Research, diet should be mechanically soft in consistency; all foods should be cut into bite-size pieces to minimize the need to chew or open the jaw widely; and chewing gum, sticky foods, and biting hard foods such as raw vegetables, candy, and nuts should be avoided (National Institutes of Health, 2010). Nutrient intake of TMD patients appears to be the same as for the general population with regard to total calories, protein, fat, carbohydrates, vitamins, and minerals. However, during times of acute pain, intake of fiber is often reduced.

## CHRONIC FATIGUE SYNDROME AND FIBROMYALGIA

Disorders such as **chronic fatigue syndrome (CFS)** and **fibromyalgia** have rheumatic symptoms. Some experts believe that CFS and fibromyalgia are variations of the same pain and fatigue syndrome. In fact, 50% to 70% of people with a diagnosis of fibromyalgia also meet the criteria for CFS and vice versa (Davis, 2005). In the US, fibromyalgia affects between 2% to 4% of the population or 12 million people (Lawrence, 2008); and CFS affects 0.007% to 2% of the general population (Avellaneda Fernández et al., 2009). Women are affected two to four times more often than men (Mayo Clinic, 2009). The etiology and pathogenic mechanisms of fibromyalgia and CFS are to date not fully understood.

CFS and fibromyalgia mimic autoimmune disorders such as SLE or hypothyroidism. Viral pathogens, immune dysregulation, central nervous system dysfunction, clinical depression, musculoskeletal disorders, and allergies have been proposed as contributing factors in CFS. In fibromyalgia, central nervous system dysfunction, mitochondrial dysfunction, nutrient deficiencies, and other systemic abnormalities have been suggested.

Mitochondrial dysfunction can result in lack of energy (ATP) for muscular work. Some symptoms include poor growth, loss of muscle coordination and muscle weakness. This can have effects on several organs and result in visual and hearing problems, learning disabilities, mental retardation, heart disease, liver disease, kidney disease,

gastrointestinal disorders, respiratory disorders, neurological problems, autonomic dysfunction, and dementia (Hassani A et al., 2010).

### Pathophysiology

In fibromyalgia, nonarticular aches at specific pressure points (See Fig 40-5) and fatigue cause disabling symptoms including muscle tenderness, sleep disturbances, fatigue, morning stiffness, numbness and tingling, symptoms of anxiety and depression, chronic headaches, irritable bowel, and irritable bladder. In 2009, new diagnostic criteria for fibromyalgia were introduced (Wolfe et al., 2011) that do not require examination for specific tender points. Rather, diagnosis is based on the combination of chronic widespread pain and a symptom severity score based on the amount of fatigue, sleep disturbances, cognitive dysfunction, and other somatic symptoms. The diagnosis of fibromyalgia often overlaps with other chronic pain syndromes, including irritable bowel syndrome, temporo-mandibular disorders, and idiopathic low back pain (Staud, 2009). In CFS, chronic fatigue is the major symptom. It lasts 6 months or longer and is accompanied by hypotension, sore throat, multiple joint pains, headaches, postexertion lethargy, muscle pain, and impaired concentration (Avellaneda Fernández et al., 2009).

### Medical Management

A treatment program for CFS should be multidisciplinary and include exercise, MNT, appropriate sleep hygiene, low-dose tricyclic antidepressants or selective serotonin reuptake inhibitors (SSRIs), and cognitive behavior therapy (Iversen et al., 2010; Lucas, 2006).

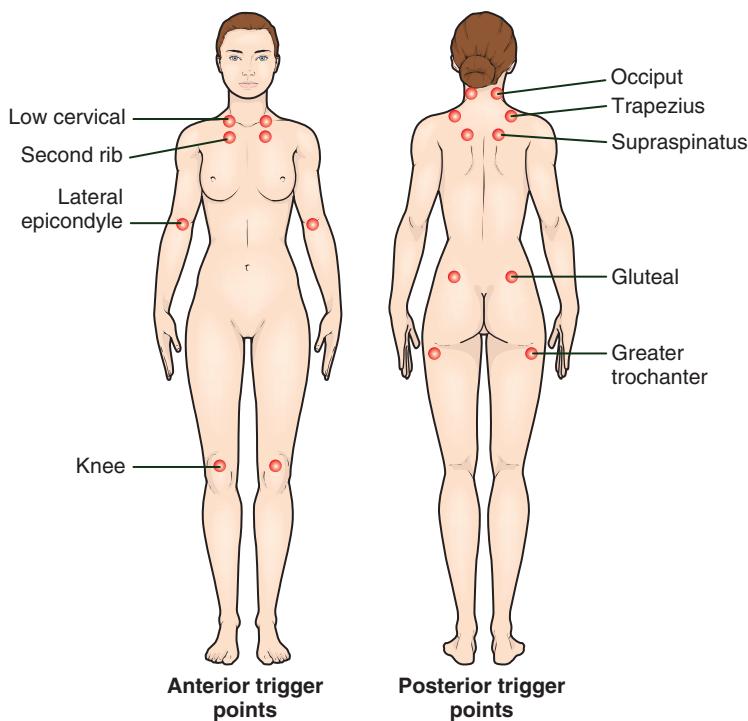

Management of concomitant disorders, including irritable bowel syndrome, depression, and migraine headaches, can improve quality of life for these patients.

Tricyclic antidepressants and SSRIs are commonly used with CFS patients although they are not FDA approved for fibromyalgia. They may be helpful in treating depression and sleep disturbances. Side effects may include agitation, dry mouth, drowsiness, and weight gain. Analgesics such as tramadol (Ultram) may be an option for treating patients with fibromyalgia. More recently, serotonin norepinephrine reuptake inhibitors (SNRIs) such as duloxetine (Cymbalta) and milnacipran (Savella) and the anticonvulsant pregabalin (Lyrica) have been suggested for fibromyalgia patients and are FDA approved for this purpose (Mease P, 2009, Argoff CE, 2010).

### Exercise

Exercise is helpful; supervised moderate-intensity graded aerobic exercise, or water aerobics (minimum 12 weeks, 3×/week) is suggested (Busch et al., 2007; Williams DA, 2009). Similarly a multidisciplinary rehabilitation program consisting of supervised exercise therapy, group pain and stress management lectures, massage therapy sessions, and a nutrition information was found to improve self-perceived health status and pain intensity (Lemstra and Olszynski, 2005).

**FIGURE 40-5** Pressure points of fibromyalgia pain.  
*(From the Clinical Slide Collection on the Rheumatic Diseases, copyright 1991, 1995, 1997. Used by permission of the American College of Rheumatology, Atlanta.)*

## Medical Nutrition Therapy

Data regarding MNT for CFS are extremely limited. When hypotension is identified medically in CFS patients, increases in sodium and fluid intakes have been suggested. Evidence is not strong for elimination diets, or for the use of nutritional supplements (Häuser et al., 2008); however, vegetarian diets could have some beneficial effects probably due to the increase in antioxidant intake (Arranz LI, 2010). The vegan “living food” diet of berries, fruits, vegetables and roots, nuts, germinated seeds, and sprouts rich in carotenoids and vitamins C and E has shown anecdotal benefits. The natural antiinflammatory quercetin also shows promise (Lucas et al., 2006), as does intake of ω-3 fatty acids (Maes et al., 2005). Weight control seems to be an effective tool to improve the symptoms in these patients (Arranz LI, 2010, Ursini F, 2011). There is no specific treatment for any of the mitochondrial myopathies, physical therapy may extend the range of movement of muscles and improve dexterity. Vitamin therapies such as riboflavin, coenzyme Q, and carnitine (a specialized amino acid) may provide subjective improvement in fatigue and energy levels in some patients (Hassani A et al., 2010).

## Alternative Therapies

Patients often seek complementary and alternative medicine treatments for relief. A survey of fibromyalgia patients found that 98% had used some type of CAM, including massage therapy, chiropractic therapy, and vitamin or mineral supplements (Wahner-Roedler et al., 2005). A recent systematic review with meta-analysis concluded that acupuncture may have a small analgesic effect but cannot be recommended as

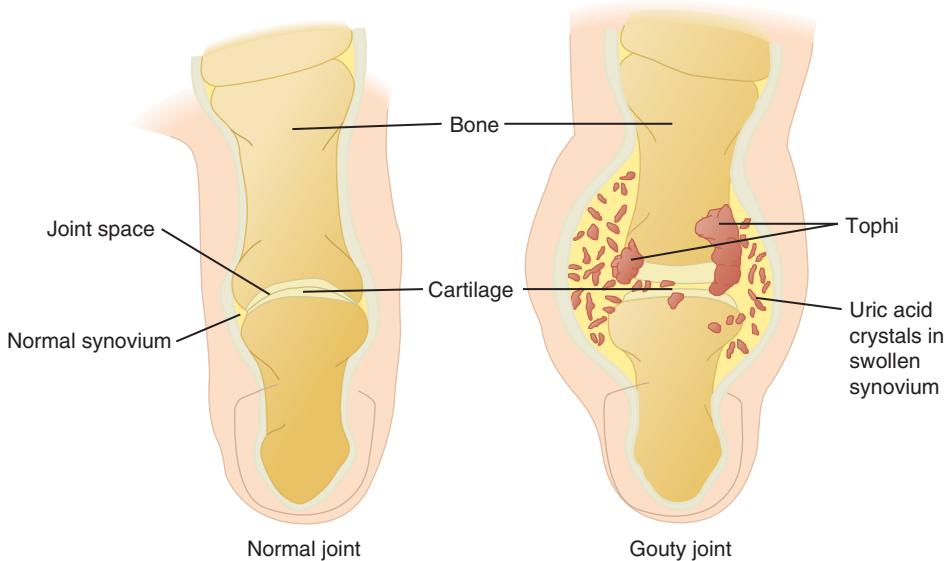

single therapy for management of fibromyalgia (Langhorst J et al., 2010). Homeopathy has also proven ineffective. (Perry R, 2010). The usual treatment options appear to be limited and generally unsatisfactory. However, cognitive behavioral therapy has been shown useful in both fibromyalgia and CFS (Williams DA, 2009, Avellaneda Fernández et al., 2009).

## GOUT

Gout, one of the oldest diseases in recorded medical history, is a disorder of purine metabolism in which abnormally high levels of uric acid accumulate in the blood (hyperuricemia). Renal disease is common, and uric acid nephrolithiasis can occur. As the disease advances, symptoms occur more frequently and are more prolonged. Unfortunately, the prevalence of gout is increasing (Hak and Choi, 2008; Lawrence et al., 2008). In the past few decades gout has approximately doubled in prevalence in the United States, and has increased in other countries. The disease usually occurs after the age of 35 years and predominantly affects men. However, it becomes equally distributed in both sexes with age (Saag and Choi, 2006).

## Pathophysiology

**Gout** is characterized by the sudden and acute onset of localized arthritic pain that usually begins in the big toe and continues up the leg. The urate deposits can destroy joint tissues, leading to chronic symptoms of arthritis (Figure 40-6). As a consequence, sodium urates are formed and deposited as tophi in the small joints and surrounding tissues.

**FIGURE 40-6** Comparison of a gouty joint and a normal joint in the toe.  
(From Black JM et al: *Medical surgical nursing*, ed 7, Philadelphia, 2005, Saunders.)

**FIGURE 40-7** Tophi on the ear of a patient who has had gout for many years. (Courtesy American College of Rheumatology, Atlanta.)

In chronic gout a classic site is the helix of the ear (Figure 40-7); a more common site is the large toe or the elbow.

Genetic factors play an important role in the pathogenesis of gout and regulation of serum uric acid levels (Riches et al., 2009). One comorbidity of gout is obesity. Although weight loss appears to be protective (Choi et al., 2005a), ketosis associated with fasting or a low-carbohydrate diet can also precipitate an attack of gout. Occasionally the disturbance follows surgery. Hypertension and use of diuretics are also risk factors (Choi et al., 2005b). Epidemiologic studies suggest an association between gout and

dyslipidemia, diabetes mellitus, and insulin resistance syndrome (Fam, 2005).

### Medical Management

The goals of treatment are to reduce the pain associated with acute attacks, to prevent future attacks, and to avoid the formation of tophi and nephrolithiasis. The primary treatment for gout involves pharmacologic therapy (colchicine, allopurinol, NSAIDs, and others depending on the acute or chronic condition and renal function). Maintaining a serum urate level of less than 6 mg/dL may reduce the risk of recurrent gout attacks.

Gout is treated with drugs that inhibit uric acid synthesis. Probenecid (Benemid) and sulfapyrazone decrease the blood uric acid level by increasing elimination through the kidneys. Allopurinol inhibits uric acid production. Both probenecid and sulfapyrazone are often used in conjunction with colchicine, a drug that has no effect on uric acid metabolism but has been shown to relieve the joint pain of gouty arthritis. Colchicine is most valuable during the acute stage but may be needed during symptom-free periods as a preventive measure. Other antiinflammatory agents such as indomethacin or phenylbutazone are sometimes used in the acute stage of gout.

### Medical Nutrition Therapy

Uric acid, derived from the metabolism of purines, constitutes a part of nucleoproteins. It appears that approximately two thirds of the daily purine load results from endogenous cell turnover, with just one third supplied by the diet (Fam, 2005). Although gout has traditionally been treated with a low-purine diet, drugs have largely replaced the need for rigid restriction of the diet. However, the patient can take an active role by adhering to the nutrition guidelines for the management of gout as well (Zhang et al., 2006).

The third National Health and Nutrition Examination Survey found that higher levels of meat and seafood consumption were associated with increased serum uric acid

**BOX 40-3****Purine Content of Foods****High Purine Content (100 to 1000 mg of Purine Nitrogen per 100 g of Food)**

Anchovies	Meat extracts
Bouillon	Mincemeat
Brains	Mussels
Broth	Partridge
Consommé	Roe
Goose	Sardines
Gravy	Scallops
Heart	Sweetbreads
Herring	Yeast (baker's and brewer's), taken as supplement
Kidney	
Mackerel	

Foods in this list should be omitted from the diet of patients who have gout (acute and remission stages).

**Moderate Purine Content (9 to 100 mg of Purine Nitrogen per 100 g of Food)**

Meat and Fish	Vegetables
Fish	Asparagus
Poultry	Beans, dried
Meat	Lentils
Shellfish	Mushrooms
	Peas, dried
	Spinach

One serving (2 to 3 oz) of meat, fish, or poultry or 1 serving ( $\frac{1}{2}$  C) of vegetables from this group is allowed daily.

**Negligible Purine Content**

Bread (white) and crackers	Fruit
Butter or margarine (in moderation)*	Gelatin desserts
Cake and cookies	Herbs
Carbonated beverages <sup>†</sup>	Ice cream
Cereal beverage (e.g., Postum)	Milk
Cereals and cereal products	Macaroni products
Cheese	Noodles
Chocolate	Nuts
Coffee	Oil
Condiments	Olives
Cornbread	Pickles
Cream (in moderation)*	Popcorn
Custard	Puddings
Eggs	Relishes
Fats (in moderation)*	Rennet desserts
Vegetables (except those in group 2)	Rice
	Salt
	Sugar and sweets <sup>†</sup>
	Tea
	Vinegar
	White sauce

Foods included in this group may be used daily.

\*Recommended in moderation because of fat content.

<sup>†</sup>Recommended in moderation because of fructose content.

levels in adults, but total protein intake was not (Choi et al., 2005a). It is prudent to advise patients to consume a balanced meal plan with limited intake of animal foods and alcohol, avoidance of high purine foods (see Box 40-3), limited consumption of sources of fructose (sweetened soft drinks and juices, candies and sweet pastries) (Li and Micheletti, 2011), and controlled food portion size, and reduced noncomplex carbohydrate intake to achieve weight loss and improve insulin sensitivity (Hayman and Marcason, 2009). High intake of fluids (8 to 16 cups of fluid/day, at least half as water) should be encouraged to assist with the excretion of uric acid and to minimize the possibility of renal calculi formation (Hayman and Marcason, 2009). Dairy products (milk, or cheese), eggs, vegetable protein, cherries, and coffee (Choi and Curhan, 2010; Li and Micheletti, 2011) appear to be protective, possibly because of the alkaline ash effect of these foods. See *Clinical Insight: Urine pH—How Does Diet Affect It?* in Chapter 36.

**SCLERODERMA**

**Scleroderma** is a chronic, systemic sclerosis or hardening of the skin and visceral organs characterized by deposition of fibrous connective tissue. Women tend to be afflicted four

times more often than men. **Raynaud's syndrome** occurs, with ischemia or coldness in the small extremities, causing difficulty in preparation and consumption of meals. SS is often also present, but there is variability among patients.

**Pathophysiology**

Scleroderma is considered an autoimmune rheumatic disease with a genetic component. Free-radical, oxidative damage from cytokines, in which fibroblast proteins are modified, is involved (Kurien et al., 2006). Gastrointestinal symptoms include gastroesophageal reflux, nausea and vomiting, dysphagia, diarrhea, constipation, fecal incontinence, and small intestine bacterial overgrowth (SIBO). Joint stiffness and pain, renal dysfunction, hypertension, pulmonary fibrosis, and pulmonary arterial hypertension are also common (Scleroderma Research Foundation, 2005).

**Medical Management**

The disease is usually, but not always progressive, and no current treatment corrects the overproduction of collagen; therefore treatment is aimed at relieving symptoms and limiting damage. Pharmacologic therapy is often involved. Some studies have been undertaken with the use of anti-TNF therapies with some promising results (Alexis and

Strober, 2005). Treatments for the pulmonary hypertension and renal crises have shown good results overall (Charles et al., 2006). The 5-year survival rate after diagnosis is 80% to 85%.

### Medical Nutrition Therapy

Dysphagia requires nutrition intervention (see Appendix 35). Dry mouth with resultant tooth decay, loose teeth, and tightening facial skin can make eating difficult (Figure 40-8). Consuming adequate fluids, choosing moist foods, chewing sugarless gum, and using saliva substitutes help moisten the mouth and may offer some relief. If gastroesophageal reflux is a concern, small, frequent meals are recommended along with avoidance of late-night eating, alcohol, caffeine, and spicy or fatty foods (see Chapter 28).

Malabsorption of lactose, vitamins, fatty acids, and minerals can cause further nutrition problems; supplementation may be required. A high-energy, high-protein supplement or enteral feeding may prevent or correct weight loss. Home enteral or parenteral nutrition is often required when problems such as chronic diarrhea persist (see Chapter 14).

## SYSTEMIC LUPUS ERYTHEMATOSUS

**Systemic lupus erythematosus (SLE)** is commonly known as *lupus*. Lupus is most prevalent in women of childbearing age and is more common in blacks and women of Hispanic, Asian, and Native American descent than in whites. Common symptoms include extreme fatigue, painful or swollen joints, unexplained fever, skin rashes, mouth ulcers, and kidney problems (NIAMS, 2009).

### Pathophysiology

SLE has a genetic predisposition and overproduction of type 1 interferon and other cytotoxic cells (Banchereau and Pascual, 2006). SLE is considered to be an autoimmune disease that affects all organ systems. Renal function is deranged in lupus, thus causing excessive excretion of protein and often renal failure.

### Medical Management

Lupus itself and the medications used (corticosteroids, NSAIDs, immunosuppressants, antimalarials) affect nutrient metabolism, needs, and excretion. Recent therapies include rituximab, a drug also used in cancer chemotherapy

**FIGURE 40-8** Facial scleroderma. Taut smooth skin over the face and reduced oral aperture of a woman with long-standing disease. (From Wigley FM, Hummers LK: Clinical features of systemic sclerosis. In Hochberg MC et al., editors: Practical rheumatology, ed 3, Toronto, 2004, Mosby.)

which causes depletion of the immune B cells. B cell depletion helps promote remission while maintaining normal levels of IgG and IgM (Smith et al., 2006).

Plaquenil, an antimalarial drug, appears to be effective in clearing up skin lesions for some individuals with lupus but has side effects that include nausea, abdominal cramping, and diarrhea. Immunosuppressives such as cyclophosphamide may be useful when there is renal involvement, but gastrointestinal and fertility problems may occur.

### Medical Nutrition Therapy

No specific dietary guidelines for managing SLE exist. Rather, the diet needs to be tailored to the individual needs of the patient. Priorities include addressing the sequelae of the disease and the pharmacologic effects on organ function and nutrient metabolism. Protein, fluid, and sodium requirements are altered as a result of disordered renal function and steroid-induced side effects. See Chapter 36. Energy needs should be tailored to the individual's dry weight. The goal should be to attain and maintain the usual body weight. Enteral nutrition support may be required in chronic cases. Yet, because there appears to be significant crossover of symptoms among several autoimmune diseases, specific MNT guidelines prove to be a challenge.

### CLINICAL SCENARIO

Beth is a 47-year-old woman who now lives with her husband after her two daughters left home to attend college. About 5 years ago, Beth noted that some of the foods she usually enjoyed preparing and eating were getting stuck in her hard palate, so she started to drink increasing amounts of water to dislodge them. Among those foods were pasta (i.e.,

linguini, lasagna), rice (fried, parboiled), cereals (breakfast cereals, granola, high-fiber content cereals), cookies, and soda crackers. The drier the meal, the more difficult it was to dislodge the foods from her palate.

Although she was very conscientious about her oral hygiene, Beth noted an increase in cavities and displacement

**CLINICAL SCENARIO—cont'd**

of her front teeth, as well as difficulties in swallowing. Soon she started to experience difficulties in biting hard fruits and vegetables (apples, peaches, carrots, cucumbers) and some cuts of meats. She also started to complain about a burning sensation in her tongue, cheeks, and gums when she ate spicy “ethnic” foods (Mexican, Asian), or drank fruit juices (orange, grapefruit, pineapple). She also presents geographic tongue, cheilitis, and cheilosis. She cannot eat a sourdough turkey sandwich without the corners of her mouth cracking and bleeding. Additionally, Beth had problems resting at night because of dryness of her nose and oral mucosa, and her eyelids were stuck together upon awakening.

Beth's history suggests a decrease in the production of saliva and tears, and she most likely has Sjögren's syndrome. Whether it is primary or secondary to systemic lupus erythematosus remains to be determined. Beth's diet seems to be low in protein, dietary fiber, vitamins (particularly of the B complex), and zinc. Due to her signs and symptoms, Beth

could easily be misdiagnosed as having severe riboflavin (B<sub>2</sub>) deficiency.

### Nutrition Diagnostic Statements

1. Difficulty Chewing
2. Inadequate Oral Intake

### Nutrition Care Questions

1. If these are Beth's nutrition diagnoses, write statements using the problem-etiology-signs and symptoms format.
2. What type of nutrition education and counseling would help Beth cope with the difficulties she experiences when eating?
3. What vitamin and mineral supplements may be needed?
4. How would you suggest use of artificial saliva?
5. What questions would you ask about her diet recall to determine compliance with your recommendations?
6. Would you consider consultation with a rheumatologist?

## CHAPTER 41

Valentina M. Remig, PhD, RD, LD, FADA  
Allisha Weeden, PhD, RD, LD

# Medical Nutrition Therapy for Neurologic Disorders

### KEY TERMS

absence seizure (petit mal)  
adrenomyeloneukodystrophy (ALD)  
agnosia  
Alzheimer's disease (AD)  
amyloid beta (A $\beta$ )  
amyotrophic lateral sclerosis (ALS)  
anomia  
anosmia  
aphasia  
apraxia  
cortical blindness  
deglutitory dysfunction  
diffuse axonal injury  
dysarthria  
dysomia  
dysphagia  
echolalia  
embolic stroke  
epidural hematoma  
epilepsy  
Guillain-Barré syndrome (GBS)  
hemiparesis  
hemianopsia  
hydrocephalus  
hyperosmia

intracranial pressure (ICP)  
ketogenic diet  
migraine syndrome  
multiple sclerosis (MS)  
myasthenia gravis (MG)  
myelopathy  
neglect  
otorrhea  
paraplegia  
paresthesia  
Parkinson's disease (PD)  
peripheral neuropathy  
rhinorrhea  
seizure  
spinal cord injury (SCI)  
subarachnoid hemorrhage (SAH)  
subdural hematoma  
syrinx  
tetraplegia  
thromboembolic event  
thrombotic stroke  
tonic-clonic (grand mal) seizure  
transient ischemic attack (TIA)  
traumatic brain injury (TBI)  
Wernicke-Korsakoff syndrome (WKS)

Neurologic diseases arise from causes that vary in complexity. Some neurologic diseases result from a simple deficiency or excess of a nutrient, whereas others have more complex causes like diabetic neuropathy, stroke, or trauma. More complicated conditions arise with the interaction of genetics with other factors, as is the case with multiple sclerosis (MS),

Parkinson's disease (PD), Alzheimer's disease (AD), and alcoholism. The medical and health history is often the most important part of a neurologic evaluation.

Numerous symptoms and malnutrition often accompany neurologic diseases. Complaints of even minor symptoms such as headaches, dizziness, insomnia, fatigue, weakness,

pain, or discomfort must be skillfully evaluated for the presence of a nutrition component in their cause and treatment. Although not all neurologic diseases have a nutritional cause, nutritional considerations are integral to effective medical and clinical management (Table 41-1). Some neurologic dysfunctions such as **peripheral neuropathy** occur secondary to disease or a deficiency of a single or several vitamins, whereas other diseases of the nervous system may be attributed to dietary deficiency or excess (Table 41-2). This chapter emphasizes conditions with nutritionally significant dysfunction.

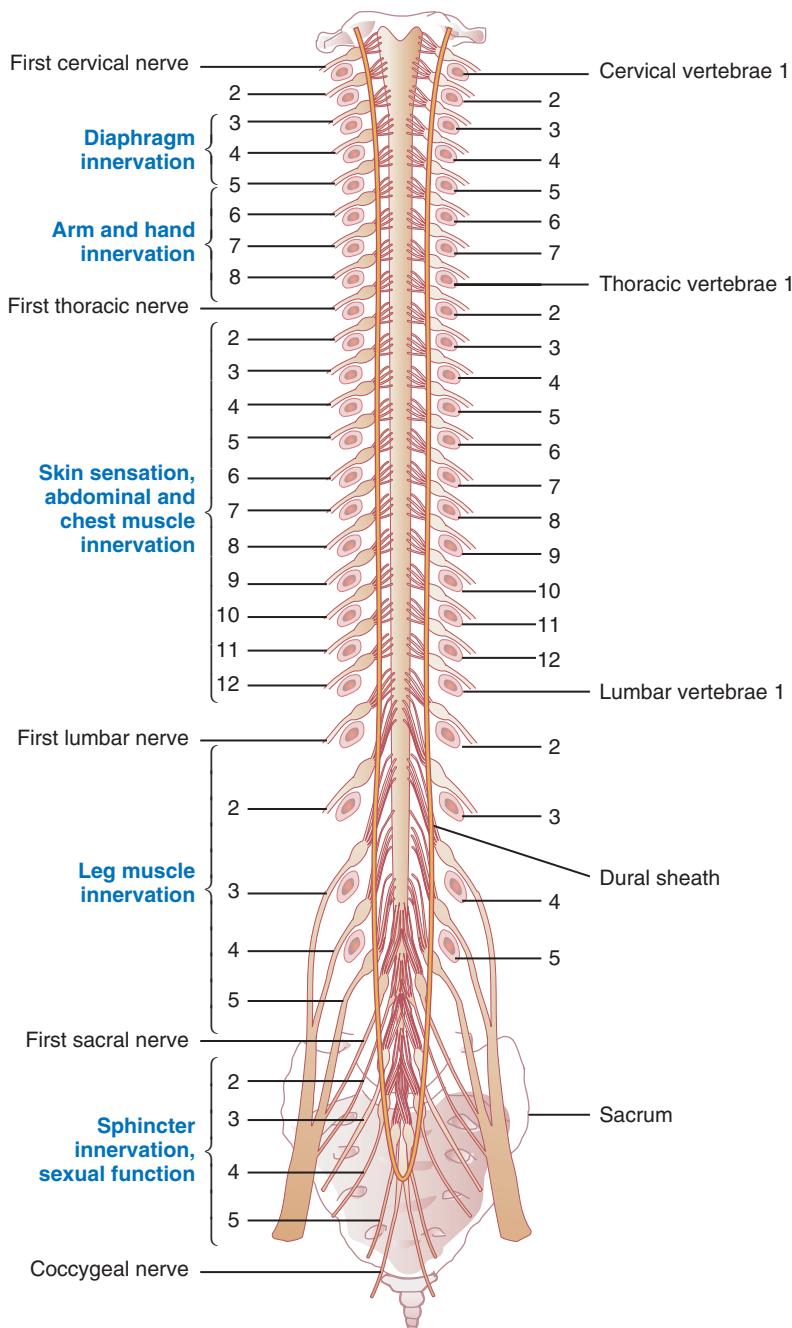

In those neurologic diseases with a nonnutritional cause, nutrition therapies are important adjuncts to effective medical management. Traumatic head, brain, and spinal cord injuries are of increasing interest to some researchers

secondary to athletic or sports trauma as well as injuries to military personnel, especially during war. Many elements of nutrition care for neurologic diseases and conditions are similar, regardless of the origin of the disease process.

## THE CENTRAL NERVOUS SYSTEM

The central nervous system (CNS) in mammals is differentiated functionally into three components so that lesions in the nervous system leave a unique “calling card” for localized dysfunction. Localizing the defect (lesion) to muscle, nerve, spinal cord, or brain is part of the medical diagnosis. Nerve tracts coming to and from the brain cross to opposite sides in the CNS (Figure 41-1). Therefore a lesion in the

**FIGURE 41-1** Spinal cord lying within the vertebral canal. Spinal nerves are numbered on the left side; vertebrae are numbered on the right side; body areas supplied by various levels are in blue.

**TABLE 41-1****Nutritional Considerations for Neurologic Conditions**

<b>Medical Condition</b>	<b>Relevant Nutrition Therapy</b>
Adrenoleukodystrophy	Dietary avoidance of VLCFAs has not been proven. Lorenzo's oil may lower VLCFA levels.
Alzheimer's disease (see Table 41-7)	Recommend antioxidants and antiinflammatory diet. Minimize distractions at mealtime. Initiate smell or touch of food. Guide hand to initiate eating.
Amyotrophic lateral sclerosis (see Table 41-9)	Provide nutrient-dense foods and ω-3 fatty acids. Intervene to prevent malnutrition and dehydration. Monitor dysphagia. Antioxidant use (vitamins C, E, selenium, methionine) is well tolerated, but not proven.
Epilepsy	Provide ketogenic diet (see Table 41-10).
Guillain-Barré	Attain positive energy balance with high-energy, high-protein tube feedings. Assess dysphagia.
Migraine headache	Follow general recommendations for food avoidance. Maintain adequate dietary and fluid intake. Keep extensive records of symptoms and foods.
Myasthenia gravis	Provide nutritionally dense foods at beginning of meal. Small, frequent meals are recommended. Limit physical activity before meals. Place temporary feeding tube.
Multiple sclerosis	Recommend antioxidants and antiinflammatory diet. Possibly recommend linoleic acid supplement. Evaluate health and especially vitamin D status of patient. Nutrition support may be needed in advanced stages. Distribute fluids throughout waking hours; limit before bed. Enteral or parenteral nutrition support needed.
Neurotrauma	Focus on drug-nutrient interactions. Minimize dietary protein at breakfast and lunch.
Parkinson's disease (see Table 41-11)	Recommend antioxidants and antiinflammatory diet. Administer vitamin B <sub>12</sub> injections. Provide diet liberal in HBV protein.
Pernicious anemia	Provide diet supplemented with Fe <sup>+</sup> , vitamin C, and B complex vitamins. Provide enteral or parenteral nutrition support.
Spinal trauma	Provide high-fiber diet, adequate hydration to minimize constipation. Provide dietary intake to maintain nutrition health and adequate weight.
Stroke	Dietary alterations for primary prevention. Maintain good nutrition status. Assess possible dysphagia. Enteral or parenteral nutrition support may be needed.
Wernicke-Korsakoff syndrome	Provide thiamin supplementation. Provide adequate hydration. Provide diet liberal in high-thiamin foods. Eliminate alcohol. Dietary protein may need to be restricted.

*Fe<sup>+</sup>*, Iron; *HBV*, high biologic value; *VLCFA*, very-long-chain fatty acid.

**TABLE 41-2****Neurologic Syndromes Attributed to Nutritional Deficiency or Excess**

<b>Nutritional Deficiency</b>		
<b>Site of Major Syndrome</b>	<b>Name</b>	
Encephalon	Hypocalcemia and tetany seizures from lack of vitamin D Impaired intellectual and cognitive function (protein-calorie deprivation) Cretinism (iodine deficiency) Wernicke-Korsakoff syndrome (thiamin deficiency)	
Optic nerve	Nutritional deficiency optic neuropathy (“tobacco-alcohol amblyopia”)	
Brainstem	Central pontine myelinolysis (sodium)	
Cerebellum	Alcoholic cerebellar degeneration	
Spinal cord	Vitamin E deficiency caused by bowel disease Combined system disease ( $B_{12}$ deficiency)	
Peripheral nerves	Tropical spastic paraparesis Beriberi (thiamin deficiency), pellagra (nicotinic acid deficiency) Hypophosphatemia	
Muscle	Tetany (vitamin D deficiency) Myopathy of osteomalacia	
<b>Nutritional Excess</b>		
<b>Syndrome</b>	<b>Condition</b>	<b>Agent</b>
Increased intracranial pressure	Self-medication	Vitamin A
Encephalopathy	Phenylketonuria	Phenylalanine
	Water intoxication	Water
	Hepatic encephalopathy	Protein (and NH <sub>3</sub> )
	Ketotic or nonketotic coma in diabetes	Glucose, insulin
Stroke	Hyperlipidemia	Lipid
Peripheral neuropathy	Hypochondriasis	Pyridoxine
	Insomnia, anxiety	Tryptophan
Myopathy	Anorexia nervosa, bulimia	Emetine, ipecac
Myoglobinuria	Constipation	Licorice

brain that affects the right arm is found on the left side of the brain. Figure 41-2 shows the segments of the brain.

Signs of weakness are the most quantifiable clinical signs of nervous system disease. The neurons in the motor strip (upper motor neurons) receive input from all parts of the brain and project their axons all the way to their destinations in the spinal cord. Axons connect to the spinal cord motor neurons (lower motor neurons). These neurons extend from the spinal cord to muscles without interruption. The location of a lesion in the nervous system can often be deduced clinically by observing stereotypical abnormalities and function of either upper or lower motor neurons (Table 41-3).

### Pathophysiology and Signs of Mass Lesions

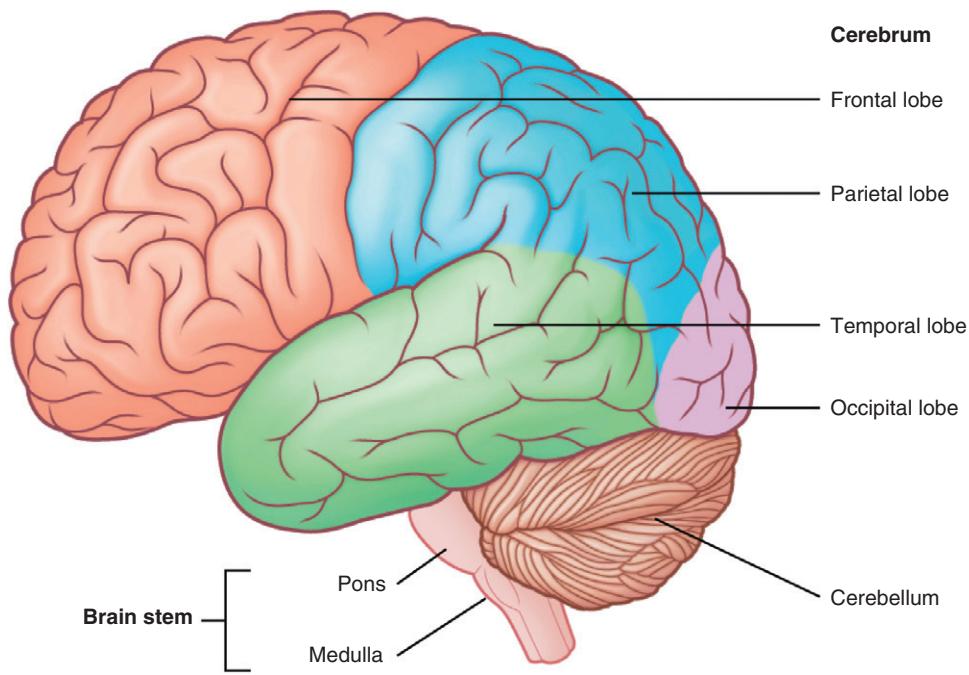

The frontal lobes in the brain are the source of the most complex activities and commonly offer the most complex presentations. Psychiatric manifestations such as depression, mania, or personality change may herald a tumor or other frontal lobe mass, either right or left. With a lesion or tumor near the skull base, one may lose the sense of smell or have visual changes because olfactory and optic nerves track

along the bottom of these frontal lobes. Chemosensory losses of smell have been described as **anosmia** (absence of smell), **hyperosmia** (increased sensitivity of smell), or **dysosmia** (distortion of normal smell).

Frontal lobes are larger, and the posterior portions of the frontal lobes contain the motor strips. Lesions in the central portion of the frontal lobes may present as a motor apraxia. A person with **apraxia** cannot properly execute a complex activity, although he or she may understand a request to perform the activity.

Temporal lobes control memory and speech; lesions there may affect these abilities, as seen with AD and stroke. Although any lesion of cerebral gray matter may produce seizures, the temporal lobes are particularly prone to seizures. A right parietal lobe mass may result in chronic inability to focus attention, thus completely ignoring the body's left side. Because speech centers are located near the junction of the left temporal, parietal, and frontal lobes, pathologic conditions in this region may cause speech problems.

The occipital lobes are reserved for vision, and dysfunction here may bring about **cortical blindness** of varying degrees. In this condition the person is unaware that he or

**FIGURE 41-2** Parts of the brain. Trauma or disease in one area may affect speech, vision, movement or eating ability. (From <http://projectflexner.sites.medinfo.ufl.edu/files/2009/04/brain-regions.jpg>. From Scully C: *Medical problems in dentistry*, ed 6, 2010, Churchill Livingstone.)

**TABLE 41-3**

**Basic Functions of Cranial Nerves**

Number	Nerve Function
Olfactory (I)	Smell
Optic (II)	Vision
Oculomotor (III)	1. Eye movement 2. Pupil constriction Eye movement
Trochlear (IV)	Eye movement
Trigeminal (V)	1. Mastication 2. Facial heat, cold, touch 3. Noxious odors 4. Input for corneal reflex Eye movement
Abducens (VI)	Eye movement
Facial (VII)	1. All muscles of facial expression 2. Corneal reflex 3. Facial pain 4. Taste on anterior two thirds of tongue
Vestibulocochlear (VIII)	Hearing and head acceleration and input for oculocephalic reflex
Glossopharyngeal (IX)	1. Swallowing 2. Gag reflex 3. Palatal, glossal, and oral sensation
Vagus (X)	1. Heart rate, gastrointestinal activity, sexual function 2. Cough reflex 3. Taste on posterior third of tongue
Spinal accessory (XI)	1. Trapezius 2. Sternocleidomastoid muscle
Hypoglossal (XII)	Tongue movement

she cannot see. Lesions at other points along the visual pathway can cause several different types of visual field deficits.

Lesions of the cerebellum and brainstem may obstruct the ventricular system where it is the narrowest. This obstruction may precipitate life-threatening **hydrocephalus**, a condition of increased **intracranial pressure (ICP)** that may quickly result in death. Other signs of hydrocephalus include trouble with balance, walking and coordination abnormalities, marked sleepiness, and complaints of a headache that is worse on awakening. Lesions in the brainstem may infiltrate any of the cranial nerves that enervate structures of the face and head, including the eyes, ears, jaw, tongue, pharynx, and facial muscles (see Table 41-3). These lesions have consequences for nutrition because the patient is often unable to eat without risking aspiration of food or liquids into the lung. Tumors or other lesions in the medulla may infiltrate respiratory and cardiac centers, and dysregulation of these centers has grim consequences.

Lesions in the spinal cord are much less common than brain tumors and ordinarily cause lower motor neuron signs at the level of the lesion and upper motor signs in segments below the level of the lesion. Spinal cord injury (SCI) is the most common pathologic condition in this region. Other examples of spinal cord abnormalities are MS, amyotrophic lateral sclerosis (ALS), tumor, syrinx (fluid-filled neurologic cavity), chronic meningitis, vascular insufficiency, and mass lesions of the epidural space.

Lesions of the pituitary gland and hypothalamus are often heralded by systemic manifestations that may include electrolyte and metabolic abnormalities secondary to adrenocortical, thyroid, and antidiuretic hormone dysregulation. Because of the proximity to the visual pathways, changes may occur in visual field or acuity. The syndrome of inappropriate antidiuretic hormone secretion (SIADH) is often a complication; volume status and hyponatremia are part of

the medical diagnosis (see Chapter 7). Because the hypothalamus is the regulatory center for hunger and satiety, lesions here may present as anorexia or overeating.

Finally, disorders of peripheral nerves and the neuromuscular junction affect one's ability to maintain proper nutrition. Disorders such as Guillain-Barré syndrome (GBS) or myasthenia gravis (MG) may counteract the efforts to maintain nutritional balance. To eat and drink effectively, many parts of the nervous system are required. A problem at any step along the way can result in an inability to meet metabolic demands.

## ISSUES COMPLICATING NUTRITION THERAPY

The nutritional management of patients with neurologic disease is complex. Severe neurologic impairments often compromise the mechanisms and cognitive abilities needed for adequate nourishment. Many patients have **dysphagia** (difficulty swallowing), and the ability to obtain, prepare, and present food to the mouth can be compromised. As a result, all patients with neurologic disease are at risk for malnutrition. Early recognition of signs and symptoms, implementation of an appropriate care plan to meet the nutritional requirements of the individual, and counseling for the patient and family members on dietary choices are essential. Regular evaluation of the patient's nutrition status and disease management are priorities, with the ultimate goal of improving outcomes and the patient's nutritional quality of life.

Nutrition assessment requires detailed histories. The diet history and mealtime observations are used to assess patterns of normal chewing, swallowing, and rate of ingestion. Weight loss history establishes a baseline weight; a weight loss of 10% or more is indicative of nutritional risk. Assessment for nutrients involved in neurotransmitter synthesis is particularly important in these patients (Table 41-4). Nutrition diagnoses common in the neurologic patient population include:

- Chewing difficulty
- Increased energy expenditure
- Inadequate energy intake
- Inadequate oral food and beverage intake
- Physical inactivity
- Poor nutrition quality of life
- Self-feeding difficulty
- Swallowing difficulty
- Underweight
- Inadequate access to food
- Inadequate access to fluid

## Meal Preparation

Confusion, dementia, impaired vision, or poor ambulation may contribute to difficulty with meal preparation, thus hindering oral food and beverage intake. Assistance with shopping and meal planning are frequently necessary.

**TABLE 41-4**

### Nutrients Involved with Neurotransmitter Synthesis

Neurotransmitter	Nutrients for Synthesis
Acetylcholine	Choline, pantothenic acid, vitamin C
Catecholamines (dopamine, epinephrine, norepinephrine)	Phenylalanine, tyrosine, niacin, folic acid, vitamin B <sub>6</sub> and vitamin C
Gamma aminobutyric acid	Glutamate, vitamin B <sub>6</sub>
Serotonin	Tryptophan, thiamin, niacin, vitamin B <sub>6</sub> , folic acid

## Self-Feeding Difficulties and Inadequate Access to Food or Fluid

With chronic neurologic diseases, a decline in function may hinder the ability for self-care and nourishment. Access to food and satisfying basic needs may depend on the involvement of family, friends, or professionals. With acute neurologic situations such as trauma, stroke, or GBS, the entire process of eating can be interrupted abruptly. The patient may require enteral nutrition for a time until overall function improves and adequate oral intake is resumed.

## Feeding Issues: Presentation of Food to the Mouth

The patient with neurologic disease may be unable to feed himself or herself because of limb weakness, poor body positioning, hemianopsia, apraxia, confusion, or neglect. Tremors in PD, spastic movements, or involuntary movements that occur with cerebral palsy, Huntington's disease, or tardive dyskinesia may further restrict dietary intake. The affected region of the CNS determines the resulting disability (Table 41-5).

If limb weakness or paralysis occurs on the dominant side of the body, poor coordination resulting from a new reliance on the nondominant side may make eating difficult and unpleasant. The patient may have to adjust to eating with one hand and also to using the nondominant hand. **Hemiparesis** is weakness on one side of the body that causes the body to slump toward the affected side; it may increase a patient's risk of aspiration.

**Hemianopsia** is blindness for one half of the field of vision. The patient must learn to recognize that he or she no longer has a normal field of vision and must compensate by turning the head. **Neglect** is inattention to a weakened or paralyzed side of the body; this occurs when the non-dominant (right) parietal side of the brain is affected. The patient ignores the affected body part, and his or her perception of the body's midline is shifted. Hemianopsia and neglect can occur together and severely impair the patient's function. A patient may eat only half of the contents of a meal because he or she recognizes only half of it (Figure 41-3).

**TABLE 41-5****Common Impairments with Neurologic Diseases**

<b>Site in the Brain</b>	<b>Impairment</b>	<b>Results</b>
Cortical lesions of the parietal lobe (perception of sensory stimuli)	Sensory deficits	Fine regulation of muscle activities impossible if the patient is unable to perceive joint position and motion and tension of contracting muscles.
Lesions of the nondominant hemisphere	Hemi inattention syndrome (neglect)	Patient neglects that side of the body.
Optic tract lesions (usually of the middle cerebral artery or the artery near the internal capsule)	Visual field cuts	Patient reads one half of a page, eats from only half of the plate, etc. (see Figure 41-3).
Loss of subcortically stored pattern of motor skills	Apraxia	Inability to perform a previously learned task (e.g., walking, rising from a chair), but paralysis, sensory loss, spasticity, and incoordination are not present.
No identification with a particular brain disorder or a specifically located lesion	Language apraxia	Inability to produce meaningful speech, even though oral muscle function is intact and language production has not been affected.
Lesion of Broca area	Nonfluent aphasia	Thought and language formulation are intact, but the patient is unable to connect them into fluent speech production.
Lesion of Wernicke area	Fluent aphasia	Flow of speech and articulation seem normal, but language output makes little or no sense.
Extensive brain damage	Global aphasia	Both expression and speech perception are severely impaired.
Brainstem lesions, bilateral hemispheric lesions, cerebellar disorders	Dysarthria	Inability to produce intelligible words with proper articulation.

From Steinberg FU: Rehabilitating the older stroke patient: what's possible? Geriatrics 41:85, 1986.

**FIGURE 41-3** A, Normal vision. B, Vision with hemianopsia.

Another potential interference with self-feeding is apraxia because the person is unable to carry out an action and follow directions. Demonstration may make it possible to do the action; however, judgment may be affected as well and can result in the performance of dangerous tasks. This makes it unsafe to leave the patient alone.

## DYSPHAGIA

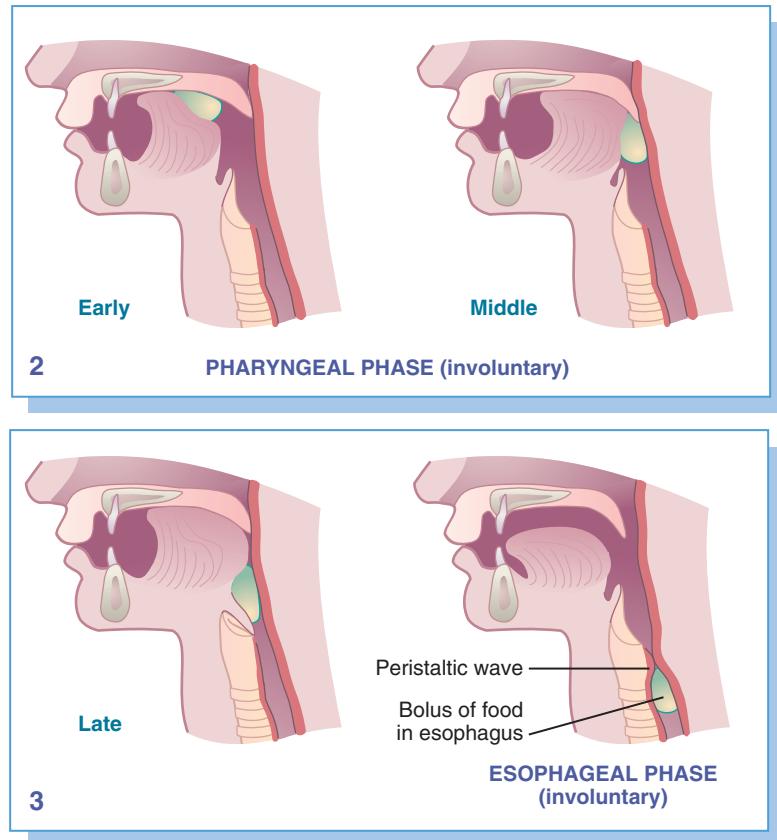

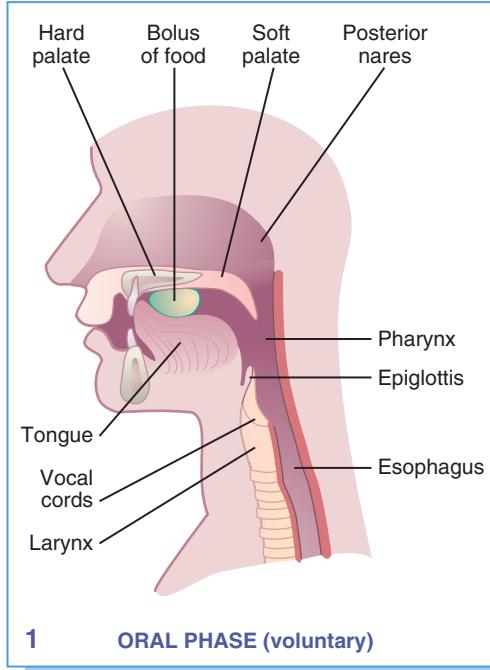

Dysphagia often leads to malnutrition because of inadequate intake. Symptoms of dysphagia may include drooling, choking, or coughing during or following meals; inability to

suck from a straw; a gurgly voice quality; holding pockets of food in the buccal recesses (of which the patient may be unaware); absent gag reflex; and chronic upper respiratory infections. Patients with intermediate or late-stage PD, MS, ALS, dementia, or stroke are likely to have dysphagia.

A swallowing evaluation by a speech-language pathologist (SLP) is important in assessing and treating swallowing disorders. The SLP is often consulted for individual patients following traumatic brain injury (TBI), stroke, or cancers of the head and neck, and for those at risk of aspiration or with other conditions that result in a lack of coordination in swallowing. Many registered dietitians (RDs) have acquired additional training in swallowing therapies to help coordinate this evaluative process.

## Phases of Swallowing

Proper position for effective swallowing should be encouraged (i.e., sitting bolt upright with the head in a chin-down position). Concentrating on the swallowing process can also help reduce choking. Initiation of the swallow begins voluntarily but is completed reflexively. Normal swallowing allows for safe and easy passage of food from the oral cavity through the pharynx and esophagus into the stomach by propulsive muscular force, with some benefit from gravity. The process of swallowing can be organized into three phases, as shown in Figure 41-4.

**FIGURE 41-4** Swallowing occurs in three phases:

1. Voluntary or oral phase: Tongue presses food against the hard palate, forcing it toward the pharynx.
2. Involuntary, pharyngeal phase: Early: wave of peristalsis forces a bolus between the tonsillar pillars. Middle: soft palate draws upward to close posterior nares, and respirations cease momentarily. Late: vocal cords approximate, and the larynx pulls upward, covering the airway and stretching the esophagus open.
3. Involuntary, esophageal phase: Relaxation of the upper esophageal (hypopharyngeal) sphincter allows the peristaltic wave to move the bolus down the esophagus.

### Oral Phase

During the preparatory and oral phases of swallowing, food is placed in the mouth, where it is combined with saliva, chewed if necessary, and formed into a bolus by the tongue. The tongue pushes the food to the rear of the oral cavity by gradually squeezing it backward against the hard and soft palate. Increased ICP or intracranial nerve damage may result in weakened or poorly coordinated tongue movements and lead to problems in completing the oral phase of swallowing. Weakened lip muscles result in the inability to completely seal the lips, form a seal around a cup, or suck through a straw. Patients are often embarrassed by drooling and may not want to eat in front of others. The patient may have difficulty forming a cohesive bolus and moving it through the oral cavity. Food can become pocketed in the buccal recesses, especially if sensation in the cheek is lost or facial weakness exists.

### Pharyngeal Phase

The pharyngeal phase is initiated when the bolus is propelled past the faucial arches. Four events must occur in

rapid succession during this phase. The soft palate elevates to close off the nasopharynx and prevent oropharyngeal regurgitation. The hyoid and larynx elevate, and the vocal cords adduct to protect the airway. The pharynx sequentially contracts while the cricopharyngeal sphincter relaxes, allowing the food to pass into the esophagus. Breathing resumes at the end of the pharyngeal phase. Symptoms of poor coordination during this phase include gagging, choking, and nasopharyngeal regurgitation.

### Esophageal Phase

The final or esophageal phase, during which the bolus continues through the esophagus into the stomach, is completely involuntary. Difficulties that occur during this phase are generally the result of a mechanical obstruction, but neurologic disease cannot be ruled out. For example, impaired peristalsis can arise from a brainstem infarct.

### Medical Nutrition Therapy

Weight loss and anorexia are key concerns with dysphagia. Observation during meals allows the nurse or RD to screen

informally for signs of dysphagia and bring them to the attention of the health care team. Environmental distractions and conversations during mealtime increase the risk for aspiration and should be curtailed. Reports of coughing and unusually long mealtimes are associated with tongue, facial, and masticator muscle weakness. Changing the

consistency of foods served may be beneficial. Keep the diet palatable and nutritionally adequate by recommending changes in food consistency. A mechanically soft or pureed consistency can reduce the need for oral manipulation and to conserve energy while eating (Box 41-1). Appendix 35 provides more detail for the National Dysphagia Diet.

## BOX 41-1

### Guidelines for Feeding the Dysphagic Patient

#### **Nonoral Intake**

##### **Level 1: Severe Dysphagia: No Oral**

##### **Feeding, Nothing by Mouth**

May exhibit one or more of the following:

- Severe retention in pharynx; unable to clear
- Severe oral stage bolus loss or retention; unable to clear
- Silent aspiration with two or more consistencies; nonfunctional volitional cough or unable to achieve swallow

##### **Level 2: Moderately Severe Dysphagia:**

##### **Maximum Assistance or Maximum Use of**

##### **Strategies With Partial Nutrition by Mouth Only**

May exhibit one or more of the following:

- Severe retention in pharynx; unable to clear or needs multiple cues
- Severe oral stage bolus loss or retention; unable to clear or needs multiple cues
- Aspiration with two or more consistencies, no reflexive cough and weak volitional cough; or aspiration with one or more consistencies, no cough, and airway penetration to cords with one or more consistencies, no cough

#### **Oral Diet: Modified Texture and Independence**

##### **Level 3: Moderate Dysphagia: Total Assist, Supervision, or Strategies; Two or More Diet Consistencies Restricted**

May exhibit one or more of the following:

- Moderate retention in pharynx that is cleared with cue
- Moderate retention in oral cavity that is cleared with cue
- Airway penetration to the level of the vocal cords without cough with two or more consistencies or aspiration with two consistencies

##### **Level 4: Mild-Moderate Dysphagia: Intermittent Supervision/Cueing; One to Two Diet Consistencies Restricted**

May exhibit one or more of the following:

- Retention in pharynx that is cleared with cue
- Retention in oral cavity that is cleared with cue
- Aspiration with one consistency; airway penetration to the level of the vocal cords with cough with two

consistencies, or airway penetration to the level of the vocal cords without cough with one consistency

##### **Level 5: Mild Dysphagia: Distant Supervision; May Need One Diet Consistency Restricted**

May exhibit one or more of the following:

- Aspiration of thin liquids only but with strong reflexive cough to clear completely
- Airway penetration midway to cords or to cords with one consistency but clears spontaneously
- Retention in pharynx that is cleared spontaneously
- Mild oral dysphagia with reduced mastication or oral retention that is cleared spontaneously

#### **Full Oral Intake of a Normal Diet**

##### **Level 6: Within Functional Limits, Modified Independence**

- Normal diet; functional swallow
- Mild oral or pharyngeal delay, retention, or trace epiglottal undercoating but independently and spontaneously compensates and clears
- May need extra time for meal
- No aspiration with different consistencies

##### **Level 7: Normal Diet in All Situations**

- Normal diet
- No strategies or extra time needed

#### **Techniques for Improving Acceptance of Dysphagia Diets**

Feeding individuals with dysphagia requires extra care and consideration. Food is enjoyed with all of the senses. Pureed meals need to look good, smell good, and taste good. Ideas to improve the sensory experience for those with dysphagia follow. Start simple and build a puree program to be creative; serve attractive meals.

##### **Aroma**

- Good-smelling food and a pleasant atmosphere may increase appetite and improve consumption.
- Serve foods seasoned with aromatic ingredients such as garlic, pepper, onions, and cinnamon.

##### **Seasoning**

- Individuals with dysphagia often have a dulled sense of taste.
- Taste all foods and enhance seasoning as needed.

**BOX 41-1****Guidelines for Feeding the Dysphagic Patient—cont'd**

- Serve foods that have stronger flavors such as chili, spaghetti, and apple pie.

**Garnishing**

- Garnishing has big visual effect, increasing the likelihood of better intake.
- Only garnish with foods appropriate for the diet consistency.
- Use sauces, gravies, and syrups. Put them in squeeze bottles to use for decorating the plates.
- Pipe garnishes around edges such as piping lettuce around the edge of a pureed sandwich.
- Cut shapes out of cranberry sauce and serve with turkey.

**Molding**

- To mold, use a thickener or a shaping or enhancing product.
- For hot foods: prepare per recipe, freeze and heat to temperature before serving.
- For cold foods: prepare per recipe, freeze, set on plate, and serve (they will thaw quickly).

**Layering or Swirling**

- Swirling vegetables together is simple and makes a great plate presentation; peas and carrots are striking together and taste great.
- Use standardized recipes to make attractive layered casseroles such as shepherd's pie, lasagna, or chicken à la king.

**Liquids**

Swallowing liquids of thin consistency such as juice or water requires the most coordination and control. Liquids are easily aspirated into the lungs and may pose a life-threatening event because aspiration pneumonia may ensue, even from sterile water in the lungs. Sterile water is no longer sterile once it is introduced to the bacterial load of the oral cavity.

If a patient has difficulty consuming thin liquids, fluid requirements must still be met. Liquids of all types can be thickened with nonfat dry milk powder, cornstarch, modular carbohydrate supplements, or commercial thickeners that contain a modified cornstarch thickener. Thick liquids that contain a high percentage of water are needed to maintain fluid balance. Fatigue and malaise are often associated with a "mild chronic dehydration" that results from decreased fluid intake. Fresh fruit is an additional source of free water.

Some long-term care facilities use the Frazier Water Protocol, which allows for drinking water in those who otherwise require thickened liquids. This protocol is based on the following assumptions:

**Piping**

- Place pureed food into a pastry bag and pipe for a lovely plate presentation.
- Keep it simple and have fun; pureed pasta can be quite attractive, for example.

**Slurries**

- Prepare slurry with thickener and juice or milk.
- Prepare slurry with a liquid that goes well with the food being prepared.
- Slurry shortcake with juice and serve with pureed strawberries.
- Slurry sugar cookies with milk.
- Slurries work well with biscuits, cakes, graham crackers, muffins, and brownies.

These are a few simple ideas when serving modified-consistency foods. Beautiful plate presentations and good-tasting foods will help maintain good intake and positive nutrition status. Good-looking and good-tasting food can help people feel more dignified in spite of their neurologic condition.

Modified from the American Dietetic Association: National dysphagia diet: standardization for optimal care, Chicago, 2003, American Dietetic Association. © American Dietetic Association. Reprinted with permission.

1. Aspiration of water poses little risk to the patient if oral bacteria associated with the development of aspiration pneumonia can be minimized.
2. Allowing free water decreases the risk of dehydration.
3. Allowing free water increases patient compliance with swallowing precautions and improves quality of life.
4. Good oral hygiene is a key ingredient of the water protocol and offers other benefits to swallowing.

Liquid intake is a concern in those with neurogenic bladder and urinary retention, a common management issue in patients with a **myelopathy** (a pathologic condition of the spinal cord) or an SCI. This predisposes the individual to urinary tract infections (UTIs) and miscalculation of fluid balance. Alternately, myelopathy and SCI may result in urinary urgency, frequency, or incontinence. To minimize these problems, distributing fluids evenly throughout the waking hours and limiting them before bedtime may help. Some patients limit fluid intake severely to decrease urgency or frequent urination. This practice increases the risk of UTI and is not recommended.

One nontraumatic cause of myelopathy and neurogenic bladder is MS, an unpredictable and severe, progressive disease of the CNS. Individuals with MS have a higher incidence of UTIs. Increased intake of cranberry juice may reduce the frequency of UTIs (see Chapter 36).

Milk is considered a liquid with unique properties. Some people associate consumption of milk with symptoms of excess mucus production; however, no evidence shows an increase in mucus production. When the dysphagic patient reports increased phlegm after milk consumption, it may actually be a consequence of poor swallowing ability rather than mucus production. Patients are encouraged to “chase” the milk products with appropriately thickened liquids to help flush the throat rather than eliminate nutrient-rich dairy products.

### Textures

As chronic neurologic disease progresses, cranial nerves become damaged, leading to neurologic deficits often manifested by dysphagia or elimination of entire food groups. Nutrition intervention should be individualized according to the type and extent of dysfunction. Vitamin and mineral supplementation may be necessary. If chewable supplements are not handled safely, liquid forms may be added to acceptable foods.

Presented with small, frequent meals, the patient may eat more. Swallowing can also be improved by carefully selecting various tastes, textures, and temperatures of foods. Juices can be substituted for water and provide flavor, nutrients, and calories. A cool temperature facilitates swallowing; therefore cold food items may be better tolerated. Carbonation may also be better tolerated because there is the beneficial effect of texture. Sauces and gravies lubricate foods for ease in swallowing and can help prevent fragmentation of foods in the oral cavity. Moist pastas, casseroles, and egg dishes are generally well tolerated. Avoid foods that crumble easily in the mouth, because they can increase choking risk.

### Enteral Nutrition

Patients with acute and chronic neurologic diseases may benefit from nutrition support. In acute disease it may be required initially until a degree of function is regained, whereas in chronic neurologic disease it may be required in the late stages to meet changing metabolic demands. Well-managed nutrition support helps to prevent pneumonia and sepsis, which can complicate these diseases. Enteral tube feedings may be necessary if the risk of aspiration from oral intake is high, or if the patient cannot eat enough to meet his or her nutritional needs. In the latter case nocturnal tube feedings can bridge the gap between oral intake and actual nutritional requirements. This should allow the normal sensation of hunger to be generated and provide freedom from tube feeding during the day.

In most instances the gastrointestinal tract function remains intact, and enteral nutrition is the preferred method of administering nutrition support. One noted exception occurs after SCI, in which ileus is common for 7 to 10 days

after the insult, and parenteral nutrition may be necessary. Although a nasogastric (NG) tube can be a short-term option, a percutaneous endoscopic gastrostomy (PEG) or gastrostomy-jejunostomy (PEG/J) tube is preferred for long-term management. These should be considered for patients whose swallowing is inadequate to ensure their nutritional health (see Chapter 14).

Malnutrition itself can produce neuromuscular weakness that negatively affects quality of life; it is a prognostic factor for poor survival. In the acutely ill but previously well-nourished individual who is unable to resume oral nourishment within 7 days, nutrition support is used to prevent decline in nutritional health and aid in recovery until oral intake can be resumed. Conversely, in the chronically ill, nutrition support is an issue that each patient must eventually address because it may result in prolonged therapy. However, adequate nutrition can promote health and may be a welcome relief to an overburdened patient.

Some patients may decline early placement of a feeding tube because of the emotional, economic, or physical effects of this choice. In advanced stages of disease the patient may refuse tube feedings, choosing not to prolong life. Nutrition support should be used when it can enhance quality of life. The health care team should alleviate patient and family concerns and support informed decisions. The patient needs to be fully informed about the effects of tube feeding on daily life. Discussion of both the advantages and disadvantages of nutrition support should be initiated with the patient and family well ahead of need. Options should include a description of feeding schedules, tube placement procedures, and appropriate training for on-going care.

## NEUROLOGIC DISEASES OF NUTRITIONAL ORIGIN

Dietary deficiencies of thiamin and niacin can directly result in neurologic symptoms. With **Wernicke-Korsakoff syndrome (WKS)**, the neurologic effect occurs secondary to alcoholism. Most neurologic symptoms arising from nutritional deficiencies can be corrected with increased food intake or supplements. See Table 41-2 through Table 41-6.

## NEUROLOGIC DISORDERS FROM TRAUMA

### Cerebrovascular Accident (Stroke)

Stroke (cerebrovascular accident) is defined as an acute onset of focal or global neurologic deficit lasting more than 24 hours; it is attributable to diseases of the intracranial or extracranial neurovasculature. Severe strokes are often preceded by **transient ischemic attacks (TIAs)**, brief attacks of cerebral dysfunction of vascular origin with no persistent neurologic defect. Stroke is the third most common cause of death in the United States and the most common cause of disability in the United States (National Institutes of Health [NIH], 2006). Old age is the most significant risk

**TABLE 41-6****Neurologic Diseases Arising From Nutritional Deficiencies**

Disease	Nutrient	Physiologic Effect	Treatment
Wet beriberi	Thiamin	Peripheral or central neurologic dysfunction	Thiamin supplementation
Pellagra	Niacin	Memory loss, hallucinations, dementia	Niacin supplementation
Pernicious anemia	Vitamin B <sub>12</sub>	Lesions occur in myelin sheaths of optic nerves, cerebral white matter, peripheral nerves	Monthly vitamin B <sub>12</sub> injections Oral vitamin B <sub>12</sub> supplements
Wernicke-Korsakoff syndrome	Thiamin	Encephalopathy, involuntary eye movements, impaired movement, amnesia	Eliminate alcohol, thiamin supplementation, adequate hydration

factor for stroke. Among modifiable risk factors, hypertension and smoking contribute most often. (See Chapter 33.) Other factors include obesity, coronary heart disease, diabetes, physical inactivity, and genetics (Goldstein et al., 2006). The high costs of stroke are attributed to the degree of disability imparted by these events.

### Pathophysiology

**Embolic stroke** occurs when a cholesterol plaque is dislodged from a proximal vessel, travels to the brain, and blocks an artery, most commonly the middle cerebral artery (MCA). In patients with dysfunctional cardiac atria, clots may be dislodged from there and embolize. In **thrombotic stroke** a cholesterol plaque within an artery ruptures, and platelets subsequently aggregate to clog an already narrowed artery. Most strokes are incited by a **thromboembolic event**, which may be aggravated by atherosclerosis, hypertension, diabetes, and gout (*Pathophysiology and Care Management Algorithm: Stroke*).

Intracranial hemorrhage occurs in only 15% of strokes but is often fatal immediately. Intracranial hemorrhage occurs more commonly in individuals with hypertension. In intraparenchymal hemorrhage, a vessel inside the brain ruptures. A variation of intraparenchymal hemorrhage is a lacunar (deep pool) infarct. These smaller infarcts occur in the deep structures of the brain such as the internal capsule, basal ganglia, pons, thalamus, and cerebellum. Even a small lacunar infarct can produce significant disability because the brain tissue in the deep structures is so densely functional. A second type of intracranial hemorrhage is **subarachnoid hemorrhage (SAH)**. SAH occurs commonly as a result of head trauma but more often as a result of a ruptured aneurysm of a vessel in the subarachnoid space.

### Medical Management

Hemorrhage is suspected when the patient presents with headache, decreased level of consciousness, and vomiting, all of which occur within minutes to hours. A thromboembolic stroke is more likely to occur when the patient is fully conscious, but onset of motor or sensory changes occurs suddenly. As with all neurologic disease, the clinical presentation depends on the location of the abnormality. An infarct of a particular cerebrovascular territory can be suspected by

seeking out various neurologic deficits. An MCA occlusion produces paresis, with sensory deficits of limbs on the opposite side of the body because this artery supplies the motor and sensory strips. If the left MCA is occluded, **aphasia**, or loss of speech or expression may be present.

In the past, treatment for embolic stroke was supportive; it focused on prevention of further brain infarction and rehabilitation. Use of thrombolytic, “clot-busting” drugs reverses brain ischemia by lysing the clots. Initiation of therapy needs to occur within 6 hours of the onset of symptoms. Use of aspirin may be of some value in preventing further cerebrovascular events, but its effectiveness varies from one patient to another.

Controlling ICP while maintaining sufficient perfusion of the brain is the treatment for intracranial hemorrhage. This may include surgical evacuation of large volumes of intracranial blood, ventricular drainage, or other neurosurgical interventions. Rehabilitation is a key component. Hemorrhage, particularly SAH, has severe functional consequences and therefore has a longer period of convalescence than ischemic stroke.

### Medical Nutrition Therapy

Primary prevention is the cornerstone for preventing stroke, in part by diet as well as by other lifestyle behaviors (Goldstein et al., 2006). Nutrition-related factors have been compiled from various large population-based prospective studies (Box 41-2).

Given the prevalence of stroke and its associated burden of disease, treatment for those afflicted with this disease cannot be ignored. In 2003 alone, strokes cost the United States an estimated \$51 billion in lost productivity and health, including \$12 billion in nursing home expenses (Centers for Disease Control and Prevention, 2006). Efforts should be directed toward maintaining the overall health of the patient. Omega-3 fatty acids may prevent some types of stroke, but should be avoided by anyone taking a blood thinner like warfarin or aspirin.

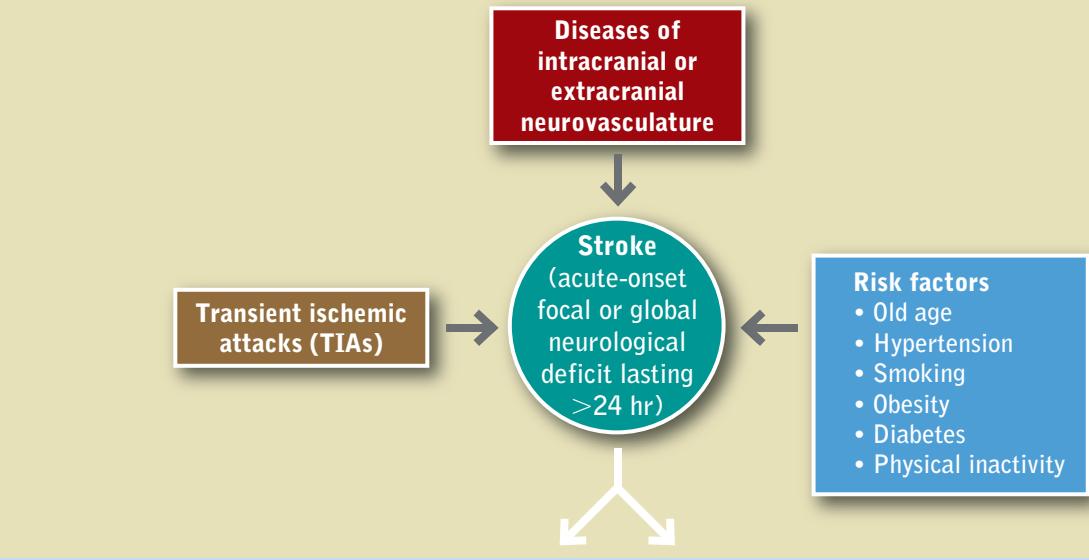

Feeding difficulties are determined by the extent of the stroke and the area of the brain affected. Dysphagia, an independent predictor of mortality, commonly accompanies stroke and contributes to complications and poor outcome from malnutrition, pulmonary infections, disability,

## PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

### Stroke

**Etiology**

**Pathophysiology**

#### Thromboembolic (Atherosclerotic)

(85% of cases)

- Consciousness unimpaired
- Sudden onset of motor or sensory findings

#### Intracranial Hemorrhage

(15% of cases)

- Headache
- Decreased level of consciousness
- Vomiting
- Often fatal immediately

**Management**

#### Medical Management

##### Embolic

- Thrombolytic drugs
- Supportive treatment

##### Hemorrhage

- Neurosurgery to relieve pressure
- Rehabilitation and physical therapy

#### Nutrition Management

- Maintain adequate nutrition
- Assess and manage dysphagia
- Vitamin and mineral supplementation as needed
- Enteral nutrition support may be necessary

increased length of hospital stay, and institutional care. In some instances nutrition support is required to maintain nutritional health until oral alimentation can be resumed. As motor functions improve, eating and other activities of daily living are part of the patient's rehabilitation process and necessary for resuming independence. Malnutrition predicts a poor outcome and should be prevented.

## HEAD TRAUMA OR NEUROTRAUMA

**Traumatic brain injury (TBI)** refers to any of the following, alone or in combination: brain injury, skull fractures, extraparenchymal hemorrhage—epidural, subdural, subarachnoid—or hemorrhage into the brain tissue itself, including intraparenchymal or intraventricular hemorrhage.

**BOX 41-2****Nutrition-Related Factors and Stroke Risk****Risk Factors for Stroke**

Body mass index >25 kg/m<sup>2</sup> in women  
 Weight gain >11 kg in 16 years in women  
 Waist-to-hip ratio >0.92 in men  
 Diabetes  
 Hypertension  
 Elevated cholesterol in hemorrhagic stroke

**Protective Factors against Stroke**

Daily consumption of fresh fruit  
 Flavonoid consumption >4.7 cups green tea/daily  
 Fish consumption and fish oil use by white and black women and by black men  
 High HDL cholesterol in ischemic stroke

risk of infection (osteomyelitis), and open skull fractures in particular carry an increased risk for meningitis because the dura mater is often violated.

Epidural and **subdural hematomas** are often corrected by surgical intervention. The volume of these lesions often displaces the brain tissue and may cause diffuse axonal injury and swelling. When the lesion becomes large enough, it may cause herniation of brain contents through various openings of the skull base. Consequent compression and ischemia of vital brain structures often rapidly lead to death.

**Medical Management**

The body's response to stress from TBI results in production of cytokines (interleukin-1, interleukin-6, interleukin-8, and tumor necrosis factor). These are elevated in the body after head injury and are associated with the hormonal milieu that negatively affects metabolism and organ function. Some of the metabolic events include fever, neutrophilia, muscle breakdown, altered amino acid metabolism, production of hepatic acute-phase reactants, increased endothelial permeability, and expression of endothelial adhesion molecules. Specific cytokines tend to cause organ demise; tissue damage has been observed in the gut, liver, lung, and brain. Overall, the molecular basis of functional recovery is poorly understood. (See Chapter 39.)

Clinical findings of brain injury often include a transient decrease in level of consciousness. Headache and dizziness are relatively common and not worrisome unless they become more intense or are accompanied by vomiting. Focal neurologic deficits, progressively decreasing level of consciousness, and penetrating brain injury demand prompt neurosurgical evaluation.

Skull fractures underneath lacerations can often be felt as a "drop off" or discontinuity on the surface of the skull, and are readily identifiable by CT scan. Basilar skull fractures are manifested by **otorrhea** (fluid leaking from the ear) or **rhinorrhea** (salty fluid dripping from the nose or down the pharynx). Other signs include raccoon eyes and Battle's sign—blood behind the mastoid process. Basilar skull fractures may precipitate injuries to cranial nerves, which are essential for chewing, swallowing, taste, and smell.

Hematomas are neurosurgical emergencies because they may rapidly progress to herniation of brain contents through the skull base and to subsequent death. These lesions may present similarly, with decreased level of consciousness, contralateral hemiparesis, and pupillary dilation. These lesions damage brain tissue by gross displacement and traction. Classically the **epidural hematoma** presents with progressively decreasing consciousness after an interval of several hours during which the patient had only a brief loss of consciousness. Subdural hematoma usually features progressively decreasing consciousness from the time of injury.

Sequelae most often include epilepsy and the postconcussive syndrome, a constellation of headache, vertigo, fatigue, and memory difficulties. Treatment for these patients can be highly complex, but the two goals of any therapeutic intervention are to maintain cerebral perfusion and to

In the United States trauma is the leading cause of death in persons up to 44 years of age, and more than one half of these deaths are the result of head injuries (Victor and Ropper, 2005). The annual incidence is estimated to be 200 per 100,000 people, with a peak frequency between 15 and 24 years of age. Motor vehicle collisions are the major source of injury.

Morbidity is high and headache is one of the most common complaints. It is difficult to accurately predict neurologic recovery. Despite intensive intervention, long-term disability occurs in a large portion of the survivors of severe head injury.

**Pathophysiology**

Brain injury can be categorized as three types: concussion, contusion, and diffuse axonal injury. A concussion is a brief loss of consciousness, less than 6 hours, with no damage found on computed tomography (CT) or magnetic resonance imaging (MRI) scans. Microscopic studies have failed to find any evidence of structural damage in areas of known concussion, although evidence of change in cellular metabolism exists. A contusion is characterized by damaged capillaries and swelling, followed by resolution of the damage. Large contusions may dramatically increase ICP and may lead to ischemia or herniation. Contusions can be detected by CT or MRI scans. **Diffuse axonal injury** results from the shearing of axons by a rotational acceleration of the brain inside the skull. Damaged areas are often found in the corpus callosum (the bridge between the two hemispheres) and the upper, outer portion of the brainstem.

Skull fractures of the calvarium and the base are described in the same manner as other fractures. *Comminution* refers to splintering of bone into many fragments. *Displacement* refers to a condition in which bones are displaced from their original positions. *Open* or *closed* describes whether a fracture is exposed to air. Open fractures dramatically increase the

regulate ICP. Perfusion and pressure control have implications for nutrition therapy.

### Medical Nutrition Therapy

The goal of nutrition therapy is to oppose the hypercatabolism and hypermetabolism associated with inflammation. Hypercatabolism is manifested by protein degradation, evidenced by profound urinary urea nitrogen excretion. Nitrogen catabolism in a fasting normal human is only 3 to 5 g of nitrogen per day, whereas nitrogen excretion is 14 to 25 g of nitrogen per day in the fasting patient with severe head injury. In the absence of nutritional intake, this degree of nitrogen loss can result in a 10% decrease in lean mass within 7 days. A 30% weight loss increases mortality rate (Brain Trauma Foundation, 2007).

Hypermetabolism contributes to increased energy expenditure. Correlations between the severity of brain injury as measured by the Glasgow Coma Scale and energy requirements have been shown. Replacement of 100% to 140% resting metabolism expenditure with 15% to 20% nitrogen calories reduces nitrogen loss (Brain Trauma Foundation, 2007). In patients medicated with barbiturates, metabolic expenditure may be decreased to 100% to 120% of basal metabolic rate. This decreased metabolic rate in pharmacologically paralyzed patients suggests that maintaining muscle tone is an important part of metabolic expenditure.

Nourishing the neurologically critically ill patient is accomplished by administering either enteral or parenteral nutrition support. Nutrition support is usually begun within 72 hours after injury and is necessary to achieve nutritional replacement by 7 days after injury (Brain Trauma Foundation, 2007). Both modes of therapy must be initiated at levels below actual requirements and increased gradually to meet nutritional requirements. For more guidelines, refer to Chapter 39.

Research in this area is exciting. An experimental dietary intervention based on a pyrazole curcumin derivative reestablishes membrane integrity and homeostasis following TBI (Sharma et al., 2010). The  $\omega$ -3 fatty acids docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA) have antioxidative, anti-inflammatory, and antiapoptosis effects, leading to neuron protection in the damaged brain (Su, 2010). Clearly, more nutrient trials are needed in this population.

## SPINE TRAUMA AND SPINAL CORD INJURY

Spine trauma encompasses many types of injuries, ranging from stable fractures of the spinal column to catastrophic transection of the spinal cord. A complete **spinal cord injury (SCI)** is defined as a lesion in which there is no preservation of motor or sensory function more than three segments below the level of the injury. With an incomplete injury there is some degree of residual motor or sensory function more than three segments below the lesion. SCI is somewhat less common than head injury; both are most often

seen in the young. Motor vehicle collisions account for one third to one half of SCIs; athletic injuries and domestic and industrial accidents account for the remainder.

### Pathophysiology

The spinal cord responds to insult in a manner similar to the brain. Bleeding, contusion, and shorn axons appear first, followed by a several-year remodeling process consisting of gliosis and fibrosis. Liquefactive necrosis may predispose to the formation of a **syrinx**, fluid collection in the center of the spinal cord; effects manifest as a slow but progressive neurologic deficit. SCIs are usually associated with spinal column fractures and ligament instability. Such processes may be amenable to either surgical or nonsurgical reduction and stabilization.

The location of the SCI and the disruption of the descending axons determines the extent of paralysis. **Tetraplegia** (formerly known as quadriplegia) exists when the injury to the spinal cord affects all 4 extremities. When the SCI location results in only lower extremity involvement it is called **paraplegia**.

### Medical Management

Spinal cord injuries have numerous clinical manifestations, depending on the level of the injury. Complete transection results in complete loss of function below the level of the lesion, including the bladder and sphincters. After the patient is stabilized hemodynamically, the doctor evaluates the degree of neurologic deficit. Patients with suspected SCI are usually immobilized promptly in the field. Complete radiographic evaluation of the spinal column is obligatory in multitrauma and unconscious patients.

In the awake patient, clinical evidence of spine compromise is usually sufficient to determine the need for further workup. CT and MRI are used to more accurately delineate bony damage and spinal cord compromise. A dismal 3% of patients with complete spinal cord insults recover some function after 24 hours. Failure to regain function after 24 hours predicts a 0% chance of reestablishment of function in the future. Incomplete spinal cord syndromes may have somewhat improved outcomes.

Morbidity and mortality rates associated with SCI have improved dramatically, particularly in the last two decades. Advances in acute-phase care have reduced early mortality and prevented complications frequently associated with early death, such as respiratory failure and pulmonary emboli. Today, fewer than 10% of patients with SCI die from the acute injury.

### Medical Nutrition Therapy

Technologic advances in enteral and parenteral feeding techniques and formulas have played a role in maintaining nutrition status of these patients. Although the metabolic response to neurotrauma has been studied extensively, the acute metabolic response to SCI has not; but it is similar to other forms of neurotrauma during the acute phase. Initially paralytic ileus may occur but often resolves within 72 hours

after injury. Because DHA and EPA have antioxidative, anti-inflammatory, antiapoptosis effects, patients may benefit from fish oil supplementation (Su, 2010).

For those who survive the injury but are disabled for life, there are significant alterations in lifestyle as well as the possibility of secondary complications. In general the number and frequency of complications, and the presence of constipation, pressure ulcers, obesity, and pain vary but will involve nutrition. Box 41-3 describes the rehabilitation potential based on the level of injury. Evidence-based practice guidelines for SCI were released in 2010 by the American Dietetic Association.

Individuals with SCI have significantly high fat mass and low lean mass. Loss of muscle tone caused by skeletal muscle paralysis below the level of injury contributes to decreased metabolic activity, initial weight loss, and predisposition to osteoporosis. Guidelines for accepted weights adjusted for paraplegia and tetraplegia are as follows: the paraplegic should weigh 10 to 15 lb less than the ideal body mass index

(BMI) would indicate; the tetraplegic should weigh 15 to 20 lb less than ideal weight dictated by the BMI. The higher the injury, the lower the metabolic rate; a lower energy requirement occurs.

Tetraplegic patients have lower metabolic rates than paraplegic patients, proportional to the amount of denervated muscle in their arms and legs, caused in part by the loss of residual motor function. In the rehabilitation phase, tetraplegics may require approximately 25% to 50% fewer calories than conventional equations predict. Thus these patients have the potential to become overweight. It has been proposed that obesity may slow the eventual rehabilitation process by limiting functional outcome.

As a consequence of bone loss resulting from the loss of mineralization caused by immobilization, SCI is associated with osteopenia and osteoporosis, and the prevalence of long-bone fractures increases. Adequate intake of vitamin D and calcium should be planned without excessive daily intakes.

### BOX 41-3

#### Key Guidelines for Managing Spinal Cord Injury

- If the patient with spinal cord injury (SCI) is in the acute phase, the registered dietitian (RD) should assess energy needs by indirect calorimetry (IC).
- Initial weight loss during the acute phase of injury may lead to weight gain in the chronic phase because of body mass redistribution.
- Patients with SCI have reduced metabolic activity because of denervated muscle. Actual energy needs are at least 10% below predicted needs.
- Because of decreased energy expenditure and caloric needs, secondary to lower levels of spontaneous physical activity and a lower thermic effect of food, adults in the chronic phase of SCI are often overweight or obese and therefore at risk for diabetes and cardiovascular disease.
- Persons of all ages with SCI appear to be at high risk for cardiovascular disease, atherogenesis, and undesirable blood lipid values. Modifiable risk factors such as obesity, inactivity, dietary factors, and smoking need to be addressed. Physical activity, including sports, swimming, electrically stimulated exercise, and body-weight supported treadmill training, may result in improvements in blood lipid parameters. Dietary intervention using the current evidence-based guide for lipid disorders should be provided by an RD.
- Nutrition care provided by the RD as part of a multidisciplinary team results in improved nutrition-related outcomes in the acute care, rehabilitation, and community settings. SCI patients experience improvements in nutrient deficiencies, nutrition problems associated with social isolation and mobility issues, overweight and obesity, bowel management, swallowing, and nutrition-related chronic diseases.
- Cranberry juice is somewhat beneficial for prevention of urinary tract infections. One cup (250 mL) three times daily can be recommended.
- A minimum of 1.5 L of fluid is recommended per day. Therapeutic diets of high fiber and adequate water intake alone often do not suffice for treatment of constipation; a routine bowel preparation program may be required. For chronic bowel dysfunction, 15 g of fiber seems more beneficial than higher levels (20-30 g).
- Maintenance of nutritional health is important because poor nutrition is a risk factor for infection and pressure ulcer development. Regular assessment of nutritional status, the provision of adequate nutritional intake, and the implementation of aggressive nutritional support measures are indicated. Reduced pressure ulcer development occurs in patients who maintain a normal weight, higher activity levels, and better serum levels of total protein, albumin, prealbumin, zinc, and vitamin D and vitamin A. Thus sufficient intake of calories, protein, zinc and vitamins C, A, and B-complex is warranted.
- When pressure ulcers are present, use 30-40 kcal/kg of body weight/day. Use 1.2 g to 1.5 g of protein/kg body weight/day in Stage II pressure ulcers and 1.5 g to 2 g of protein/kg body weight/day for Stage III or IV pressure ulcers. See Table 21-2 in Chapter 21. Fluid requirements should be at least 1 mL fluid per kcal provided; increase if air-fluidized beds are used and when losses are increased for any reason.

## NEUROLOGIC DISEASES

### Adrenomyeloneukodystrophy

#### Pathophysiology

**Adrenomyeloneukodystrophy (ALD)** is a rare congenital enzyme deficiency that affects the metabolism of very-long-chain fatty acids (VLCFAs) in young men. This leads to accumulation of VLCFAs, particularly hexacosanoic acid (C26:0) and tetracosanoic acid (C24:0) in the brain and adrenal glands (Deon et al., 2006). The incidence is 1 in 21,000 male births and 1 in 14,000 female (Moser, 2006). It is an X-linked recessive disorder characterized by myelopathy, peripheral neuropathy, and cerebral demyelination. The adult variant, adrenomyeloneuropathy, has chronic distal axonopathy of spinal cord and peripheral nerves marked by cerebral inflammatory demyelination; head trauma is an environmental factor that is detrimental in those people genetically at risk (Raymond et al., 2010). The mental and physical deterioration progresses to dementia, aphasia, apraxia, dysarthria, and blindness.

#### Medical Management

Clinical manifestations usually occur before age 7 and may manifest as adrenal insufficiency or cerebral decompensation.

**Dysarthria** (impairment of the tongue or other muscles needed for speech) and dysphagia may interfere with oral alimentation. Bronzing of the skin is a late clinical sign. With adrenal insufficiency, replacement of steroids is indicated, which may improve neurologic symptoms and prolong life. Numerous therapies have been directed at the root of the disorder but have been disappointing. The selective use of bone marrow transplant is one current therapy; gene therapy holds promise for the future.

#### Medical Nutrition Therapy

Nutritional therapy by dietary avoidance of VLCFAs does not lead to biochemical change because of endogenous synthesis. A specialty altered fatty acid product, Lorenzo's oil (C18:1 oleic acid and C22:1 erucic acid), lowers the VLCFA level. Although the clinical course is not significantly improved, a slower decline in function may result.

### Alzheimer's Disease

Alzheimer's Disease (AD) is the most common form of dementia, with varying patterns and rates of cognitive decline (Soto et al., 2005). It is named after Alois Alzheimer, who first described the clinical features and pathologic changes of this degenerative brain disease in 1907. The incidence rate of new cases of AD is similar for both sexes and throughout the world, but prevalence is three times higher in women (who tend to live longer than men). Age is the most important risk factor for AD; the number of people with the disease doubles every 5 years beyond age 65. More than 35 million people worldwide are estimated to have this disease (Querfurth, 2010). Given the increase in the number of adults living longer, the personal, familial, financial, and clinical effects of AD are staggering.

#### Etiology

At least three genes have been discovered that cause early-onset, familial AD; other genetic mutations have been associated with age-related, sporadic AD. Apolipoprotein-E4 (Apo-E4) is a protein located on chromosome 19; it binds  $\beta$ -amyloid and is involved in the transport of cholesterol. Thus, Apo-E4 has both cardiovascular and nutritional implications. Damage to key mitochondrial components (Kidd, 2005), oxidative stress, impaired insulin signaling, elevated homocysteine (Hcy), low folate, and high serum cholesterol may be causal factors.

Lead, iron, aluminum, copper and zinc have been implicated in AD pathogenesis because they catalyze the production of free radicals and induce dementia (Ramesh et al., 2010). With aging, changes occur in neurogenesis and Reelin signaling (Shetty, 2010). Inflammatory pathways have been implicated as well. Beclin 1 is a protein involved in the regulation of autophagy, a cellular degradation and maintenance pathway that is reduced in patients with AD (Jaeger and Wyss-Coray, 2010).

#### Pathophysiology

**Alzheimer's disease (AD)** is a progressive, neurodegenerative disease characterized in the brain by abnormal clumps of **amyloid beta (A $\beta$ )** peptide and neurofibrillary tangles (NIH, 2006). The early symptoms of AD, forgetfulness and loss of concentration, are often missed because they are misinterpreted as natural signs of aging (see *Pathophysiology and Care Management Algorithm: Alzheimer's Disease*).

AD begins gradually; advances; and eventually leads to confusion, personality and behavior changes, and impaired judgment. Manifestations of AD result in a progressive dementia, with increasing loss of memory, intellectual function, disturbances in speech, loss of independence, disordered eating behavior, and weight change.

Persons with poor physical function seem to have a high risk for developing AD (Wang, 2006). Initially, day-to-day events are forgotten, possessions are misplaced, and appointments are missed but memories are retained. Cerebral function declines, mostly evident after pronounced memory loss. Names of objects are forgotten (**anomia**), words spoken by others are repeated (**echolalia**), and comprehension is mostly lost (**agnosia**). Over time, motor skills deteriorate, evidenced by changes in reflexes and a shuffling gait. When AD reaches the terminal stage, bowel and bladder controls are lost; limb weakness and contractures occur; intellectual activity ceases. The patient becomes completely incapacitated in a vegetative state as death approaches.

#### Medical Management

AD is diagnosed by histopathologic examination. The disease includes a preclinical disease stage, a mild cognitive impairment stage, and finally dementia. For the first time in decades, new diagnostic and treatment guidelines are being developed by the National Institute on Aging. Nonsteroidal antiinflammatory drugs (NSAIDs) or aspirin in combination with intake of food sources of vitamin E, other antioxidants,

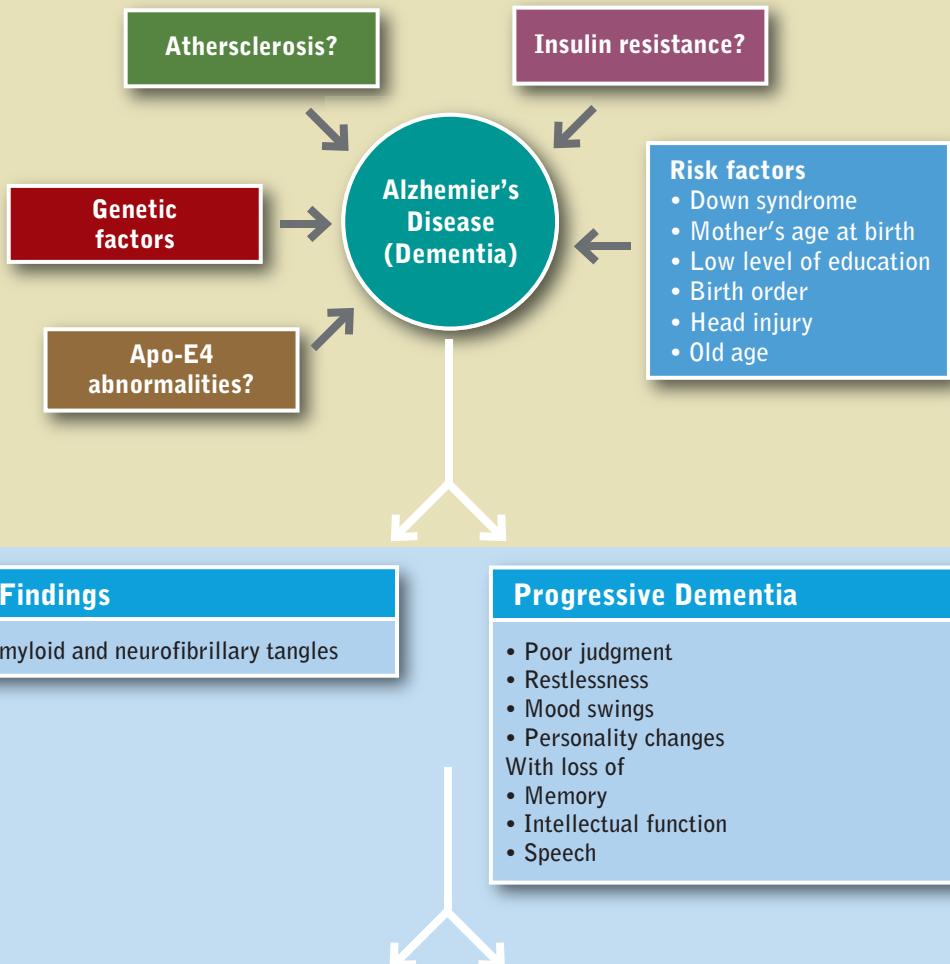

## PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

### Alzheimer's Disease

ETIOLOGY

PATHOPHYSIOLOGY

MANAGEMENT

and ω-3 fatty acids are currently most effective (Shetty, 2010).

Cerebral vasodilators, stimulants, levodopa, and mega-doses of vitamins remain unproven and drug treatment is experimental. Tacrine, the first cholinesterase inhibitor approved by the Food and Drug Administration (FDA) for

treatment of AD, gives only modest improvement in function and cognition. Some other medications are used to suppress aberrant behavior, disturbed sleep, anxiety, or agitation. Collaborative interdisciplinary care may improve behavioral and psychological symptoms (Callahan et al., 2006). Stem cell transplantation may be tested for

improving memory (Shetty, 2010). Other therapies are under development; see *New Directions: Supplementation of Cell Membrane Phospholipids in Alzheimer's Disease?*

### Medical Nutrition Therapy

Diets rich in saturated fatty acids and alcohol, and deficient in antioxidants and vitamins promote the onset of the disease; diets rich in unsaturated fatty acids, vitamins, antioxidants, wine, curcumin and some spices suppress its onset by scavenging free radicals and preventing oxidative damage (Ramesh et al., 2010). Proper inclusion of antioxidants and specific nutrients may protect the AD patient. A 2010 report of a 4 year prospective cohort study of 2148 community-based adults (65+ years of age) found that persons with a diet characterized by higher intakes of salad dressing, nuts, fish, tomatoes, poultry, cruciferous vegetables, fruits, and dark and green leafy vegetables were less likely to acquire AD than those eating diets of high-fat dairy products, red meat, organ meats, and butter (Gu et al., 2010). Because several dietary polyphenols are known to chelate metals, their routine use may also be protective (Ramesh et al., 2010). Garlic may be neuroprotective (Chauhan, 2005) and resveratrol prevents neuronal decline with aging (Anekonda, 2006; Ramesh et al., 2010). See also Figure 41-5.

**Problems with Self-Feeding, Oral Intake, and Weight Management.** A wide range of neurologic functions are impaired that interfere with eating. Cognitive losses impair attention span, reasoning, and judgment; the ability to recognize feelings of hunger, thirst, and satiety decline. As the disease progresses, attention span decreases, and meals may be forgotten as soon as they are eaten or may not be eaten at all. Dehydration is also a problem; recognizing thirst and then seeking water is neglected.

Although a gluttonous appetite and weight gain may develop in some individuals with AD, generally weight loss is the norm. Whether increased resting metabolic rate or

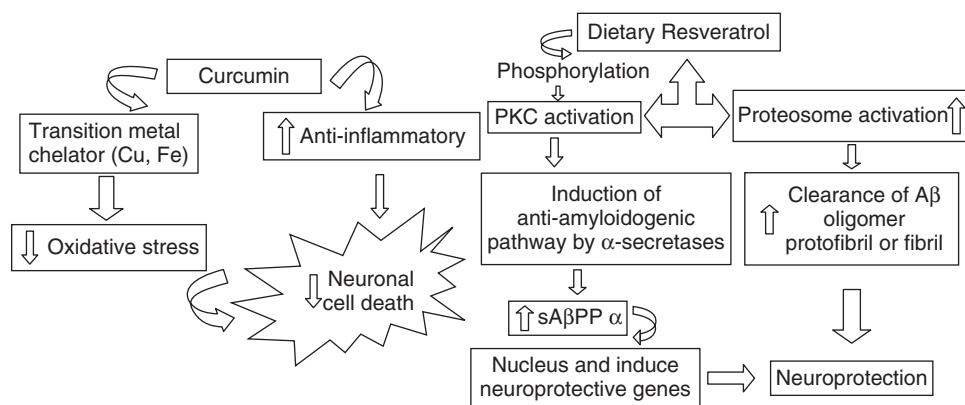

### ↗ NEW DIRECTIONS

#### Supplementation of Cell Membrane Phospholipids in Alzheimer's Disease?

Choline, a B-vitamin, makes several metabolic contributions to cell membrane phospholipids. Because of this, it is gaining interest for its potential role in neurologic conditions. It is a precursor for phosphatidylserine and phosphatidylcholine, phospholipids located in the cell membrane of cells, including nerve cells (Tan, 1998; Zeisel, 2010).

Phosphatidylserine is located on the cytosol side of the lipid membrane of cells. It has been studied in brain health, and may offer neuro-protection by inhibiting the formation of beta amyloid fragments in those with AD. Early studies using bovine phosphatidylserine showed positive results in those with cognitive decline. Due to fears of mad cow disease, the compound was replaced in studies with a soy-based phosphatidylserine which is not exactly the same. Weak evidence supporting improvement in age-related memory impairment has been associated with the soy-based compound, but overall results are inconclusive and more research is needed (Wollen, 2010).

Because phosphatidylcholine may offer protection, it is noted that precursor CDP-choline shows promise. There may be positive effects on memory and behavior in patients with various forms of dementia, including AD. Longer term studies are needed to investigate full benefits (Fioravanti et al, 2010). Nonetheless, nutritional intake can be enhanced. Choline is found in eggs (especially yolks), beef (especially brains and liver), fish, pork, poultry, beans, nuts, peas, and soy products.

**FIGURE 41-5** The role of curcumin and resveratrol in neuroprotection.

*Left:* Curcumin has multiple biologic effects: it chelates transition metals (iron and copper) and acts as an antioxidant and antiinflammatory molecule, protecting from oxidative stress.

*Right:* Resveratrol favors phosphorylation in protein kinase C, activating the nonamyloidogenic pathway of A $\beta$ PP cleavage, and this leads to reduction in A $\beta$  formation. sA $\beta$ PP $\beta$ , a product of A $\beta$ PP cleavage, gets translocated to the nucleus and modulates the genes. All these events favor neuronal cell survival. (From Ramesh BN et al: *Neuronutrition and Alzheimer's disease*, J Alzheimer's Dis 19:1123, 2010. With permission from IOS Press.)

A $\beta$ , Amyloid beta; PKC, protein kinase C; sAPP $\beta$ , secreted fragment of amyloid protein precursor beta.

increased energy expenditure from constant pacing causes weight loss is unclear. For others, eating is neglected and inadequate oral intake results from impaired self-feeding. In still other cases weight loss may be secondary to frequent infections. Weight loss in turn increases the risk of skin ulcers and consequently decreases quality of life.

Mealtimes should be kept simple. Noise can be distracting; the radio or television should be turned off during mealtime. Food may need to be placed on small plates or bowls and served one at a time so as not to offer too many choices. As social inhibitions decrease, the patient may take another person's food, consume inedible items or spoiled foods, or drink hazardous fluids. AD patients should be closely supervised during meals.

With sensory losses, perception of the surrounding world and related auditory, visual, or tactile recognition are distorted; this is called *agnosia*. Visual agnosia, the inability to recognize food, is manifested by not eating. The touch or smell of food is needed to initiate eating responses. Another sensory loss is the inability to recognize food when it is served in a bowl the same color as the food item. Use of colored bowls and plates that are in contrast to the color of the food may be necessary so that food can be distinguished from the place setting. Patients may have difficulty using eating utensils, but may model behaviors when demonstrated by staff or caregivers.

Motor losses occur during the course of the illness. Some clients may need hand guidance to initiate eating, then verbal cues to continue. As motor skills decline, the patient may be able to use only a spoon. However, eating utensils should not be removed prematurely because this may contribute to agitation, excessive disability, inadequate oral intake, and eventual weight loss. In addition, motor skills should be assessed routinely. Finger foods may be used, but only if the patient has no difficulty with chewing or swallowing. If the patient is inclined to swallow large boluses of food, finger foods are not appropriate. Although adaptive equipment is sometimes useful, it may be unfamiliar to the patient. As end-stage disease approaches, swallowing often becomes impossible. Dysphagia should be managed to prevent aspiration.

Frequent snacks, nutrient-dense foods, and nutrition supplements are needed to combat weight loss. Behavior modification and the use of altered food choices can improve quality of life. Evaluation of nutrition status is needed throughout the stages of AD to ensure that objectives of nutrition therapy continue to be met. Table 41-7 lists additional interventions.

Further, a succinct listing of drugs commonly used in the treatment of various neurologic diseases is shown in Table 41-8.

### Amyotrophic Lateral Sclerosis

**Amyotrophic lateral sclerosis (ALS)** is the most common motor system disease. ALS is also called *Lou Gehrig disease*, after the famous baseball player afflicted with the disease. The incidence is 2 in 100,000 (International Alliance of ALS, 2010). ALS involves a progressive denervation, atrophy,

and weakness of muscles; hence the name *amyotrophy*. The prevalence is constant throughout the world, but men are affected more than women. The average age of onset is the mid-50s, and it is usually found in the 40- to 70-year age group.

### Etiology

The cause of ALS is not clear. Genetic analysis of patients with familial, chromosome 21-linked ALS suggests that misfolding mutations in the copper-zinc superoxide dismutase (SOD1) gene may be involved (Nordlund and Oliveberg, 2006). Risk factors related to occupation, trauma, diet, or socioeconomic status are not consistent. However, it has been noted in several studies that elevated Hcy has neurotoxic effects. Because high Hcy levels induce oxidative stress and stimulate excitotoxic receptors, they damage motor neurons (Zoccolella et al., 2010).

### Pathophysiology

The pathologic basis of weakness in ALS is the selective death of motor neurons in the ventral gray matter of the spinal cord, brainstem, and in the motor cortex. Clinical manifestations are characterized by generalized skeletal muscular weakness, atrophy, and hyperreflexia. The natural course for ALS is unpleasant. Decline is relentless and without remissions, relapses, or plateaus; it finally progresses to death usually in 2 to 6 years (Czaplinski, 2006).

The typical presentation is evidenced with both lower motor neuron (weakness, wasting, fasciculation) and upper motor neuron deficits (hyperactive tendon reflexes, Hoffman signs, Babinski signs, or clonus). Muscle weakness begins in the legs and hands and progresses to the proximal arms and oropharynx. As these motor nerves deteriorate, almost all of the voluntary skeletal muscles are at risk for atrophy and complete loss of function. The loss of spinal motor neurons causes the denervation of voluntary skeletal muscles of the neck, trunk, and limbs, resulting in muscle wasting, flaccid weakness, involuntary twitching (fasciculations) and loss of mobility.

Progressive loss of function in cortical motor neurons can lead to spasticity of jaw muscles, resulting in slurred speech and dysphagia. The onset of dysphagia is usually insidious. Swallowing difficulties usually follow speech difficulties. Although some weight loss is inevitable given the muscle atrophy, consistent or dramatic loss may be an indicator of chewing difficulties or dysphagia (Bulat and Orlando, 2005). Eye movement and eye blink are spared, as are the sphincter muscles of the bowel and bladder; thus incontinence is rare. Sensation remains intact and mental acuity is maintained.

### Medical Management

No currently known therapy cures the disease. To lower high serum Hcy levels, short-term treatment with a high dose of methylcobalamin ( $B_{12}$ ) shows promise (Zoccolella et al., 2010). Use of folate and antioxidant treatments should also be investigated. Although mechanical ventilation can extend the life of patients, most decline this option. Quality

**TABLE 41-7****Practical Interventions for Eating-Related Behavioral Problems Common in Individuals with Dementia**

<b>Behavioral Problem</b>	<b>Intervention</b>
Attention or concentration deficit	Verbally direct client through each step of eating process; place utensils in hand. Make food and fluids available and visible.
Combative, throws food	Identify provocative agent, remove. Feeder stands or sits on nondominant side. Provide nonbreakable dishes with suction holder. Give one food at a time. Reward appropriate mealtime behavior.
Chews constantly	Tell client to stop chewing after each bite. Serve soft foods to reduce the need to chew. Offer small bites.
Eats nonedible things	Remove nonedibles from reach; provide finger foods. Use edible centerpiece or table decorations.
Eats too quickly	Set utensils down between bites. Offer food items separately. Offer bulky foods that require chewing. Use a smaller spoon or cup.
Eats too slowly	Monitor eating place and provide verbal cues: "chew," "take a bite." Serve first to allow more time. Use insulated dishes to maintain proper temperatures.
Forgetful or disoriented	Follow simple routines. Provide constant environment. Provide assigned seating. Minimize distractions and limit choices.
Forgets to swallow	Tell client to swallow. Feel for swallow before offering next bite. Stroke upward on larynx.
Inappropriate emotional expression	Engage in conversation; ignore emotional display. Provide a quiet environment.
Paces	Sit beside client at table. Change dining location. Provide aerobic exercise before meals. Offer finger foods.
Plays in food	Use cups with covers or spouts. Serve one food at a time. Fill glass or plate half full at refill. Offer finger foods.
Shows paranoia	Use cups with covers or spouts. Provide structured routine. Present food in consistent manner. Serve foods in closed containers.
Spits	Do not put medicine in food. Evaluate chewing and swallowing ability. Tell client not to spit.
Will not go into dining room	Place client away from others who would be offended. Provide mealtime supervision. Ask why; change dining location. Provide a single dining partner versus a group. Serve meals in room if needed.

**TABLE 41-9****Nutritional and Metabolic Changes During the Progression of Amyotrophic Lateral Sclerosis**

	Early Phase	Late Phase
Pathophysiology	Cycles of muscle denervation, muscle catabolism and atrophy, reinnervation, and protein synthesis	Net muscle catabolism and atrophy
Functional status	Mild functional restriction of physical activity Mild impairment of respiration	Progressive limitation of physical activity Increased work of ventilation
Nutritional and metabolic changes	Positive nitrogen balance Normal resting energy expenditure Probable neutral energy balance	Negative nitrogen balance Increased resting energy expenditure Decrease in body fat

From Kasarskis EJ et al: Nutritional status of patients with amyotrophic lateral sclerosis: relation to the proximity of death, Am J Clin Nutr 63:130, 1996.

of life is poor in advanced ALS and supportive comfort measures are primarily used.

### Medical Nutrition Therapy

There are decreases in body fat, lean body mass, muscle power, and nitrogen balance and an increase in resting energy expenditure as death approaches. Some of the nutritional changes during the different stages of ALS are noted in Table 41-9.

Hypermetabolic status and increased resting energy expenditure measurements have been noted. The relationship between dysphagia and respiratory status is important. As ALS progresses, a progressive loss of function in bulbar and respiratory muscles contributes to oral and pharyngeal dysphagia. In late stages, when the respiratory status is impaired, alternative tube placement besides PEG may be required.

The clinician should become familiar with common clinical findings in ALS to prevent secondary complications of malnutrition and dehydration. The functional status of each

patient should be monitored closely so that timely intervention with the appropriate management techniques can be started. In particular, dysphagia should be monitored closely. Oropharyngeal weakness affects survival in ALS by placing the patient at continuous risk of aspiration, pneumonia, and sepsis and by curtailing the adequate intake of energy and protein. These problems can compound the deteriorating effects of the disease. The Amyotrophic Lateral Sclerosis Severity Scale is often used to assess the functional level of swallowing, speech, upper and lower extremities. Once the severity of deficits has been identified, appropriate interventions can be implemented (see *Focus On: Dysphagia Intervention for Amyotrophic Lateral Sclerosis*).

### Epilepsy

**Epilepsy** is a chronic condition characterized by unprovoked, recurring seizures that disrupt the nervous system. **Seizures** (or convulsions) are intermittent derangements in brain function caused by abnormal electrical activity of a group of brain cells, and present with apparent clinical

## ◎ FOCUS ON

### Dysphagia Intervention for Amyotrophic Lateral Sclerosis

Strand and colleagues (1996) outlined dysphagia intervention on a continuum of five stages that correlate to the amyotrophic lateral sclerosis (ALS) severity scale. They include:

- 1. Normal Eating Habits (ALS Severity Scale Rating 10-9).** Early assessment and intervention are critical for maintaining nutritional health in ALS. This is the appropriate time to begin educating the patient, before the development of speech or swallowing symptoms. Hydration and maintenance of nutritional health are critical at this stage. Fluid intake of at least 2 q/day is important. Dehydration contributes to fatigue and thickens saliva. For patients with spinal ALS, emphasis on fluids is important because they may intentionally limit fluid intake because of difficulties with toileting. The diet history is helpful to assess patterns of normal chewing, swallowing, and the rate of ingestion. Weight loss history establishes a baseline weight. A weight loss of 10% or more is indicative of nutritional risk.
- 2. Early Eating Problems (Severity Scale Rating 8-7).** At this point patients begin to report difficulties eating; reports of coughing and unusually long mealtimes are associated with tongue, facial, and masticator muscle weakness. Dietary intervention begins to focus on modification of consistency, avoidance of thin liquids, and use of foods that are easier to chew and swallow.
- 3. Dietary Consistency Changes (Severity Scale Rating 6-5).** As symptoms progress, the oral transport of food becomes difficult as dry, crumbly foods tend to break apart and cause choking. Foods that require more chewing (e.g., raw vegetables or steak) are typically avoided. As dysphagia progresses, ingestion of thin liquids, especially water, may become more problematic. Often the patient has fatigue and malaise, which may be associated with a mild chronic dehydration resulting from a decreased fluid intake. Dietary intervention should change food consistency to mechanically soft or pureed (see Appendix 35) to reduce the need for oral manipulation and to conserve energy. Small, frequent meals may also increase intake. Thick liquids that contain a high percentage of water, as well as attempts to increase fluid intake, need to be emphasized to maintain fluid balance. Popsicles, gelatin, ice, and fresh fruit are additional sources of free water. Liquids can be thickened with a modified cornstarch thickener. Swallowing can be improved by emphasizing taste, texture, and temperature. Juices can be substituted for water to provide taste, nutrients, and calories. A cool temperature facilitates the swallowing mechanism; therefore cold food items may be better tolerated; heat

does not provide the same advantage. Carbonation may also be better tolerated because of the beneficial effect of texture. Instructions for preventing aspiration should be addressed: safe swallowing includes sitting bolt upright with the head in a chin-down position. Concentrating on the swallowing process can also help reduce choking. Avoid environmental distractions and conversation during mealtime; however, families should be encouraged to maintain a normal mealtime routine. As dysphagia progresses, the limitation of food consistencies may result in the exclusion of entire food groups. Vitamin and mineral supplementation may be necessary. If chewable supplements are not handled safely, liquid forms may be added to acceptable foods. Fiber may also need to be added along with fluids for constipation problems.

- 4. Tube Feeding (Severity Scale Rating 4-3).** Dehydration will occur acutely before malnutrition, a more chronic state, is exhibited. This may be an early indication of the need for nutrition support. Weight loss from muscle wasting and dysphagia will eventually lead to placement of a percutaneous endoscopic gastrostomy (PEG) tube for nutrition and protection against aspiration caused by dysphagia. Enteral nutrition support is preferred because the gastrointestinal tract should be functioning properly. Given the progressive nature of ALS, placing feeding tubes with signs of dysphagia and dehydration is better than initiating this therapy later, after the patient has become overtly malnourished or when respiratory status is marginal. The decision of whether to place a feeding tube for nutrition support is part of the decision-making process each patient must face. Adequate nutriture can maintain health of the individual longer and may be a welcome relief for the patient. The purpose of nutrition support should be to enhance the quality of life. Long-term access should be considered via a PEG or percutaneous endoscope jejunostomy tube (see Chapter 14).
- 5. Nothing by Mouth (Severity Scale Rating 2-1).** The final level of dysphagia is reached when the patient can neither eat orally nor manage his or her own oral secretions. Although saliva production is not increased, it tends to pool in the front of the mouth as a result of a declining swallow response. Once the swallowing mechanism is absent, mechanical ventilation is required to manage saliva flow. Tube feeding is permanent at this stage.

Data from Strand EA et al: Management of oral-pharyngeal dysphagia symptoms in amyotrophic lateral sclerosis, Dysphagia 11:129, 1996.

symptoms and findings. It is estimated that 2.3 million individuals in the United States have epilepsy; 45,000 children younger than age 15 develop epilepsy each year according to the Epilepsy Foundation (2006).

### Pathophysiology

Most seizures begin in early life, but a resurgence of epileptic events occurs after age 60. The first occurrence of a seizure in adults should prompt investigation into a cause. A clinical workup usually reveals no anatomic abnormalities, and the cause of the seizure may remain unknown (idiopathic). Seizures before age 2 are usually caused by developmental defects, birth injuries, or a metabolic disease (see Chapters 44 and 45). The medical history is the key component for suggesting further avenues of diagnostic investigation and potential treatments, especially in children. An electroencephalogram can help to delineate seizure activity. It is most helpful in localizing partial complex seizures.

### Medical Management

The dramatic **tonic-clonic (grand mal) seizure** is the most common image of a seizure (lasting 1 to 2 minutes), yet numerous classifications of seizures, each with a different and often less dramatic clinical presentation, exist. A generalized seizure involves or appears to involve the entire brain cortex from its beginning phases. The tonic-clonic seizure comes under this heading. After such a seizure the patient wakes up slowly after a time; he or she will be groggy and disoriented for minutes to hours after the event. This is termed the *postictal phase* and is characterized by deep sleep, headache, confusion, and muscle soreness.

The **absence seizure (petit mal)** is also generalized in nature. A patient with absence seizures may appear to be daydreaming during an episode, but he or she recovers consciousness within a few seconds and has no postictal fatigue or disorientation. Partial seizures occur when there is a discrete focus of epileptogenic brain tissue. A simple partial seizure involves no loss of consciousness, whereas a complex partial seizure is characterized by a change in consciousness. Failure of partial seizure control may prompt consideration of seizure surgery. A localized focus resected from nonessential brain renders a patient seizure free in 75% of cases.

Determining the seizure type is key to implementing effective therapy. Generalized seizures are ordinarily managed with valproate or phenytoin. Phenytoin metabolism has unusual kinetics; thus toxic levels may be attained with very small dosage adjustments. These drugs interact with other drugs metabolized in the liver and may cause liver damage. Liver enzymes and serum drug levels must be monitored periodically. Gabapentin is rapidly gaining popularity because of its safety and ease of use. Carbamazepine or phenytoin can usually control partial seizures. Use of just one antiseizure medication is recommended initially, resorting to combination therapies only when needed.

Medications used in anticonvulsant therapy may alter the nutrition status of the patient (see Chapter 9 and Appendix 31). Phenobarbital has been associated with decreased

intelligence quotient when used in children. It is occasionally considered for use after failure of other antiepileptic drugs. Phenobarbital, phenytoin, and primidone interfere with intestinal absorption of calcium by increasing vitamin D metabolism in the liver. Long-term therapy with these drugs may lead to osteomalacia in adults or rickets in children, and vitamin D supplementation is recommended. Folic acid supplementation interferes with phenytoin metabolism; thus it contributes to difficulties in achieving therapeutic levels. If folic acid supplementation is necessary, it should be consistent, and medication adjusted accordingly.

Phenytoin and phenobarbital are bound primarily to albumin in the bloodstream. Decreased serum albumin levels in malnutrition or advanced cirrhosis limits the amount of drug that can be bound. This results in an increased free drug concentration and possible drug toxicity even with a standard dose.

Absorption of phenobarbital is delayed by the consumption of food; therefore administration of the drug must be staggered around mealtimes if it is used. Continuous enteral feeding slows the absorption of phenytoin, thus necessitating an increase in the dose to achieve a therapeutic level. Stopping the tube feeding 1 hour before and 1 hour after the phenytoin dose is generally recommended. Whenever tube feedings are stopped, the dose of phenytoin needs to be adjusted to avoid toxicity.

### Medical Nutrition Therapy

A **ketogenic diet** can be used for treatment of all types of seizures in children with intractable epilepsy in whom drug therapies have failed. The ketogenic diet has minimal side effects, and risks of the diet are low blood sugar, upset stomach at first caused by the high amounts of fat, and constipation. The long-term risk of kidney stones is rare; elevated serum cholesterol is usually temporary and disappears with discontinuation of the diet; and growth, which is sometimes slowed while on the diet, resumes at the child's normal rate (Patel et al., 2010). Although the diet is very demanding and requires continued effort even after the first phase, it completely controls epilepsy in one third of the children whose seizures are otherwise uncontrollable (Groomes et al., 2011). Practical guidelines for implementing the diet have been released by the American Academy of Neurology and the American Epilepsy Society and can be retrieved from the Epilepsy Foundation website (Kossoff et al., 2009).

The diet is designed to create and maintain a state of ketosis (Bough and Rho, 2007). The beneficial effect in epilepsy may be caused by a change in neuronal metabolism; ketones may inhibit neurotransmitters, thus producing an anticonvulsant effect in the body. To begin the diet the individual usually fasts in the hospital for 24 to 72 hours until ketonemia is produced as measured by the level of beta-hydroxybutyrate in the blood. For many patients, if the diet is going to work, it usually works during this initial period with a reduction in seizures; however, sometimes the child needs to follow the subsequent ketogenic diet for 3

**TABLE 41-10****Typical Ketogenic Diet Pattern**

	<b>Amount (g)</b>	<b>Fat (g)</b>	<b>Protein (g)</b>	<b>Carbohydrates (g)</b>	<b>Energy (kcal)</b>

Created by Marta Mazzanti, RD, Seattle Children's Hospital, Seattle, WA.

months before there are any reductions in seizure activity. It should also be noted that antiepileptic drugs are not stopped when administering the ketogenic diet.

In the traditional approach, once ketosis is established, caloric intake is resumed in a ratio of 3:1 or 4:1, meaning that there are 3 or 4 g of fat for every 1 g of protein and carbohydrate combined in the diet. With a 4:1 ratio, the diet is calculated so that at least 80% of the kilocalories are from fat. Protein is calculated to provide appropriate intake for growth (approximately 1 g/kg/day). Carbohydrates are added to make up the remaining small portion of calories.

The majority of the diet is composed of fresh meats, eggs, cheese, fish, heavy whipping cream, butter, oils, nuts, and seeds. Vegetables and fruits are added in small amounts, within the current diet prescription (Table 41-10). Ketosis is monitored by regular measurements of serum  $\beta$ -hydroxybutyrate. Even though goal levels are

patient specific, most individuals need to be in the range of 35–60 mg/L (4–7 mmol/L) for seizure control. A carbohydrate-free multiple vitamin and mineral supplement is necessary to ensure that the diet is nutritionally complete. However, additional vitamins and minerals are often necessary, including calcium, vitamin D, and selenium.

Other nonfood items such as sugar-containing toothpaste, shampoo, and lotions need to be avoided. It is important that the diet be strictly followed; the smallest amount of extra carbohydrate can cause a breakthrough seizure. The child should be monitored, because too rapid a rate of weight gain can decrease ketosis and reduce effectiveness.

A variation of the ketogenic diet is the modified Atkins diet in which calories are not restricted, but carbohydrates are drastically limited to 10 to 20 g/day. The ratio of fat to protein and carbohydrate is usually 1:1. It appears that the best results are achieved when the diet begins with 10 g/day

of carbohydrate and is then adjusted upward, always maintaining ketosis (Porta et al., 2009; Weber et al., 2009).

Another modification of the traditional ketogenic diet is the medium-chain triglyceride (MCT) oil-based ketogenic diet, used frequently in the United Kingdom and Canada, in which some of the long-chain fats of the traditional diet are replaced with MCTs. MCT oil is an odorless, colorless, tasteless oil and was originally used as a means of improving the palatability of the diet. A greater amount of nonketogenic foods such as fruits and vegetables and small amounts of bread and other starches can be allowed because ketosis from MCT can be more readily achieved with a lower percentage of fat in the diet. MCT can be added in to the classic ketogenic diet and modified Atkins diet to increase ketosis. Coconut oil can also be used as a source of MCT to increase palatability, but it contains only 45% to 50% MCT so more may be needed. MCT oil or coconut oils are also added if the serum triglycerides are too high with the use of the traditional ketogenic diet.

Initiating the ketogenic diet is intense. Further, the diet may be unpalatable as well as complex, requiring weighing and measuring of all foods, thus making compliance difficult to achieve. To be successful, children may benefit from behavioral techniques, whereas parents most often require substantial psychosocial support. Attention required during the fine-tuning phase varies and is affected by the patient's health status, growth, and development. For the child whose epilepsy is controlled by the diet, complying with the diet is much easier than dealing with devastating seizures and injuries.

Discontinuation of the diet can be considered after 2 to 3 years, especially if the child has been seizure free for a year, although seizure control medication may still be necessary. The person is "weaned" off the ketogenic diet over a period of several months to a year as small amounts of carbohydrates are added with observation for seizure reoccurrence.

### Guillain-Barré Syndrome

**Guillain-Barré syndrome (GBS)** is an acute-onset, inflammatory, demyelinating polyneuropathy of the proximal motor nerves, including the cranial nerves and the diaphragm. The incidence is approximately 2 in 100,000.

#### Etiology

In 60% of cases the disorder follows an infection, surgery, or an immunization. Some of the more common organisms are *Campylobacter jejuni* and *Mycoplasma*. Several pathologic varieties exist, and the nature of the distinction is related to the segment of the immune system that is inflicting nerve damage. The clinical course of GBS is similar regardless of subtype, although GBS after a *Campylobacter* infection tends to be more severe.

#### Pathophysiology

Relatively symmetric weakness with **paresthesia** usually begins in the legs and progresses to the arms. The loss of function in affected nerves occurs because of demyelination.

Myelin is the specialized fatty insulation that envelops the conducting part of the nerve, the axon. In GBS the immune system recognizes myelin and mounts an attack against it. Presumably myelin shares a common characteristic with the pathogen from the antecedent infection; thus the immune system cannot differentiate what is foreign (the pathogen) from what is native (myelin). When the nerve is demyelinated, its ability to conduct signals is severely impaired, resulting in neuropathy.

#### Medical Management

GBS reveals itself in a matter of days. The most common sequence of symptoms is areflexia (absence of reflexes), followed by proximal limb weakness, cranial nerve weakness and respiratory insufficiency. These symptoms normally peak by 2 weeks but may progress up to 1 month. Medical diagnosis is ordinarily made on clinical grounds, but nerve conduction studies are also beneficial. Before the clinical course is apparent, myelopathic disorders need to be considered.

Because of the precipitous progression of GBS, hospitalization is usually necessary. Vital capacity and swallowing function may rapidly deteriorate such that intensive care is sometimes necessary. Intubation and respiratory support should be instituted early in respiratory decline to avoid the need for resuscitation. Plasmapheresis, the exchange of the patient's plasma for albumin, is often helpful to reduce the load of circulating antibodies. Intravenous immunoglobulin or steroids have been shown to be of benefit.

#### Medical Nutrition Therapy

Guillain-Barré syndrome evolves quickly; during the acute stage, the metabolic response of GBS is similar to the stress response that occurs in neurotrauma. Energy needs assessed by indirect calorimetry may be as high as 40 to 45 kcal/kg and protein needs twice the usual amount. Supportive nutritional care should be offered to attenuate muscle wasting.

For a small percentage of patients, oropharyngeal muscles may be affected, leading to dysphagia and dysarthria. In this situation, a visit by the dietitian at mealtime can be a valuable way to observe difficulties the patient may have with chewing or swallowing. Specific difficulties warrant evaluation by a swallowing specialist. The speech therapist can evaluate the degree of dysphagia and make appropriate dietary recommendations pertaining to texture. As the patient recovers, it is important to discuss safe food handling and future prevention of *C. jejuni* infection.

#### Migraine Syndrome

The **migraine syndrome** is defined clinically as an episodic intense, throbbing head pain that lasts from 4 to 72 hours. It is usually on one side of the head and becomes worse with exertion. It may be accompanied by nausea and classically is associated with a prodrome of visual disturbances or unusual olfactory and gustatory perception. Most persons report an associated transient visual aura, including flashing lights. Migraines are more common between the

ages 15 and 55 and affect women three times more often than men.

## Pathophysiology

Although the cause is unknown, migraine headache is thought to be vascular in origin and follows a family history of migraines or of visual prodromata. The leading theory proposes that dural blood vessels become dilated and the pulsatile blood flow through these vessels distends and irritates the highly pain-sensitive dura mater. This would explain the throbbing quality of the headache. An inflammatory component to migraine headache is also present along with mitochondrial dysfunction (Gardner and Boles, 2010).

## Medical Management

Treatment depends on the frequency of attacks and the presence of comorbid illness. A thorough history is the key to medical diagnosis. To qualify for a diagnosis of migraine headache, the headache must be throbbing, episodic, and supremely intense. A history of intercurrent nausea, vomiting, photophobia, and visual or olfactory auras should be present.

Numerous medicines are used to prevent or abort migraine, indicating a less than clear understanding of its pathophysiologic characteristics. NSAIDs are often the first line, followed by sympathomimetics and serotonin agonists such as sumatriptan. Prophylaxis can include calcium channel antagonists,  $\beta$ -adrenergic blockers, and serotonin antagonists.

## Medical Nutrition Therapy

Migraine attacks are triggered by a variety of factors, including food, drugs, odors, and changes in sleep habits; they respond to a variety of treatments (Dowson et al., 2006). Because foods implicated in one individual may not trigger attacks in another and food intolerance thresholds vary over time, generalized recommendations about food avoidance are ill advised. There has been attention to biogenic amines such as tyramine or phenylethylamine in foods as triggers of migraine headaches. A trial of a tyramine- or phenylethylamine-restricted diet may be recommended for some clients (see Box 9-3 in Chapter 9 for biogenic amine-containing foods), but evidence is not clear on its success (Sun-Edelstein and Mauskop, 2009a). Because suspect food items or “trigger foods” can only be correctly identified if eliminated and then reintroduced into the diet, the dietitian can strategize on this approach. See Chapter 27 for a food diary form to record intake and timing of symptoms, and to determine which foods may be a problem. In some patients dehydration may be the instigator; one simple measure is to drink more water (at least 2–3 cups) to rehydrate (Blau, 2005; Spigt et al., 2005).

Many patients try herbs or botanical products or nutritional supplementation to manage their headaches. Feverfew is used by many migraine sufferers, even though a Cochrane Database Review has not proven its efficacy. Because of their roles in energy metabolism, two nutrients,

riboflavin and coenzyme Q<sub>10</sub>, have been suggested (Hershey et al., 2007; Schiapparelli et al., 2010). Magnesium has also been shown effective in treating migraine headaches (Sun-Edelstein and Mauskop, 2009b).

## Myasthenia Gravis

**Myasthenia gravis (MG)** is the most well-known disorder of the neuromuscular junction. The neuromuscular junction is the site on the striated muscle membrane where a spinal motor neuron connects. Here the signal from the nerve is carried to the muscle via a submicron-size gap, a synapse. The molecule that carries the signal from the nerve ending to the muscle membrane is acetylcholine (Ach), and acetylcholine receptors (AchRs) populate the muscle membrane. These receptors translate the chemical signal of Ach into an electrical signal that is required for contraction of muscle fibers. MG is one of the most well-characterized autoimmune diseases, a class of disorders in which the body's immune system raises a response to AchRs. The incidence of MG is low, approximately 14 in 100,000 people.

## Pathophysiology

In MG the body unwittingly makes antibodies to AchR. These antibodies are the same that fight off colds and give immunity. The AchR antibodies bind to AchR and make them unresponsive to Ach. There is no disorder of nerve conduction and no intrinsic disorder of muscle. The characteristic weakness in MG occurs because the signal of the nervous system to the muscle is garbled at the neuromuscular junction. Patients with MG commonly have an overactive thymus gland. This gland resides in the anterior thorax and plays a role in the maturation of B lymphocytes, the cells that are charged with synthesizing antibodies.

## Medical Management

Relapsing and remitting weakness and fatigue, varying from minutes to days, characterize MG. The most common presentation is diplopia (double vision) caused by extraocular muscle weakness, followed by dysarthria, facial muscle weakness, and dysphagia. Dysphagia or swallowing disorders (resulting from fatigue following mastication) may cause malnutrition. Less commonly, proximal limb weakness in the hips and shoulders may be present. Severe diaphragmatic weakness can result in respiratory difficulty. No involvement of sensory nerves occurs.

Anticholinesterases are medicines that inhibit acetylcholinesterase, thus serving to increase the amount of Ach in the neuromuscular junction. Corticosteroids are immunosuppressive. Removal of the thymus results in symptomatic improvement in most patients.

## Medical Nutrition Therapy

Chewing and swallowing are often compromised in MG. Because this compromise occurs with fatigue, it is important to provide nutritionally dense foods at the beginning of meals before the patient tires. Small, frequent meals that are easy to chew and swallow are helpful. Difficulties holding a

bolus on the tongue have also been observed, suggesting that foods that do not fall apart easily may be better tolerated. For patients treated with anticholinesterase drugs, it is crucial to time medication with feeding to facilitate optimal swallowing.

Physical activity should be limited before mealtime to ensure maximum strength to eat a meal. It is also important not to encourage food consumption once the patient begins to tire because this may contribute to aspiration. If and when respiratory crisis occurs, it is usually temporary. Nutrition support via NG tube may be implemented in the interim to assist in maintaining vital functions of the patient until the crisis subsides. Once extubated, a swallow evaluation using cinefluoroscopy is appropriate to assess the degree of **deglutitory dysfunction** (swallowing irregularity) or risk of aspiration associated with an oral diet.

### Multiple Sclerosis

**Multiple sclerosis (MS)** is a chronic disease that affects the CNS and is characterized by destruction of the myelin sheath, the function of which is transmission of electrical nerve impulses. Multiple areas of optic nerves, spinal cord, and brain undergo “sclerosis” whereby myelin is replaced with sclera or scar tissue. No single test can ascertain whether a patient has MS; however, diagnostic criteria (McDonald criteria) were developed for use by practicing clinicians (Polman et al., 2005).

The signs and symptoms of MS are easily distinguished, and they recur over the natural history of this disease. In the worst scenario MS can render a person unable to write, speak, or walk. Fortunately the majority of patients are only mildly affected. The prevalence is lower in equatorial areas, southern United States, and southern Europe; it is higher in Canada, northern Europe, and the northern United States. MS is the most common demyelinating disorder of the CNS, affecting 2.5 million people worldwide (Freedman, 2006).

### Pathophysiology

The precise cause of MS remains undetermined. A familial predisposition to MS has been noted in a minority of cases. However, familial tendency is not well established and no consistent pattern of Mendelian inheritance has emerged (Victor and Ropper, 2005). Geographic latitude and diet are therefore implicated. Epidemiologic studies have linked the incidence of MS to geographic location and sunshine exposure. The degree of sunlight exposure catalyzes the production of vitamin D<sub>3</sub> in the skin. This form of vitamin D<sub>3</sub> is a selective immune system regulator and may inhibit MS progression (Mark and Carson, 2006). Further, in cross-sectional evaluations of MS and vitamin D, an increased prevalence of clinical vitamin D deficiency was associated with decreased bone density (Mark and Carson, 2006). Given the current evidence of the potential benefits of vitamin D, it appears to be reasonable and safe to consider vitamin D supplementation adequate to achieve normal levels in patients with MS (Solomon and Whitham, 2010).

### Medical Management

Fluctuating symptoms and spontaneous remissions make treatments difficult to evaluate. Currently no proven treatment for changing the course of MS, preventing future attacks, or preventing deterioration exists. Initially recovery from relapses is nearly complete, but over time, neurologic deficits remain. Therefore measures to maximize recovery from initial attacks or exacerbations, prevent fatigue and infection, and use all of the available rehabilitative measures to postpone the bedridden stage of disease are imperative. Physical and occupational therapies are standard for weakness, spasticity, tremor, uncoordination, and other symptoms.

Drugs for spasticity can be initiated at a low dose and cautiously increased until the patient responds. Physical therapy for gait training and range-of-motion exercises helps. Steroid therapy is used in treating exacerbations; adrenocorticotropic hormone (ACTH) and prednisolone are the drugs of choice. However, treatment is not consistently effective and tends to be more useful in cases of less than 5 years' duration. Side effects of short-term steroid treatment include increased appetite, weight gain, fluid retention, nervousness, and insomnia. Reduced cerebrospinal fluid and serum levels of vitamin B<sub>12</sub> and folate have been noted in MS patients who receive high-dose steroids. Methotrexate may also be used with ACTH, causing anorexia and nausea. Drug therapies may be a challenge (see Chapter 9 and Appendix 31).

### Medical Nutrition Therapy

Several dietary regimens for managing MS have been studied, all of which have yielded equivocal results. Various diets such as allergen-free, gluten-free, pectin-free, fructose-restricted, raw food diet, megadoses of micronutrients, zinc phosphates with calcium, and other combinations have been ruled ineffective. The RD's evaluation of the patient to maximize nutritional intake is imperative. Vitamin D status should be assessed by measuring 25-hydroxy vitamin D and supplementation may be warranted; total intake should be monitored from multivitamin and mineral supplements and fortified foods (Brown, 2006).

As the disease progresses, neurologic deficits and dysphagia may occur as the result of damaged cranial nerves. Thus diet consistency may need to be modified from solids to mechanically soft or pureed items, even progressing to thick liquids to prevent aspiration. Impaired vision, dysarthria, and poor ambulation make meal preparation into a difficult task. In this situation reliance on comfort foods or prepackaged, single-serving, or convenience foods often permits independent preparation of meals. Given the chronic nature of this debilitating disease, patients may require enteral nutrition support.

Neurogenic bladder is common, causing urinary incontinence, urgency, and frequency. To minimize these problems, distributing fluids evenly throughout the waking hours and limiting them before bed is helpful. Some patients limit fluid intake severely to decrease frequency of urination but

thereby increase the risk of UTIs. UTIs are common in patients with MS, and some patients increase their intake of cranberry juice as a form of self-treatment (see Chapter 36).

Neurogenic bowel can cause either constipation or diarrhea, and incidence of fecal impaction is increased in MS. A diet that is high in fiber with additional prunes and adequate fluid can moderate both problems.

### Parkinson's Disease

**Parkinson's disease (PD)** is a progressive, disabling, neurodegenerative disease, first described by James Parkinson in 1817. PD is characterized by slow and decreased movement, muscular rigidity, resting tremor, postural instability, and decreased dopamine transmission to the basal ganglia. Although the natural history of this disease can be remarkably benign in some cases, approximately 66% of patients are disabled within 5 years, and 80% are disabled after 10 years (Victor and Ropper, 2005).

PD is one of the most common neurologic diseases in North America; it affects approximately 1% of the population older than 65 years of age. The incidence is similar across socioeconomic groups, although PD is less common in blacks and Asians in comparison with whites. It most commonly occurs between the ages of 40 and 70.

### Pathophysiology

Although the cause of PD remains unclear, it is multifactorial and the pathogenesis is well described. It involves an interaction of inheritance with environmental factors. There is a marked loss of dopaminergic neurons (pigmented cells) in the substantia nigra, as well as tyrosine hydroxylase, the rate-limiting enzyme for dopamine.

In studying the brains of people with PD after they die, accumulations of protein called *Lewy bodies* (named after the doctor who first found them) are found. More than 10 genes causing familial PD have been identified. Genetic testing for PD is not warranted at this time, but continued investigations hold promise.

The role of endogenous toxins from cellular oxidative reactions has emerged because aging has been associated with a loss of neurons containing dopamine and an increase in monoamine oxidase. When metabolized (enzymatic oxidation and autooxidation), dopamine produces endogenous toxins (hydrogen peroxide and free radicals), causing peroxidation of membrane lipids and cell death. In the presence of an inherited or acquired predisposition, severe oxidative injury can lead to substantial loss of dopaminergic neurons similar to that observed in PD.

Several other environmental factors have also been implicated as causal factors of PD. The connection between smoking and a lowered risk for PD has been evaluated, but results are inconsistent (Zhang et al., 2006). In older patients, drug-induced PD may occur as a side effect of neuroleptics or metoclopramide (see Chapter 9 and Appendix 31).

Nutrient-related findings are biologically plausible and support the hypothesis that oxidative stress may contribute to the pathogenesis of PD (Czlonkowska et al., 2010). The relationships of folate, elevated plasma homocysteine levels,

fiber and caloric deficits are being evaluated. Vitamin B<sub>6</sub> intake may also decrease the risk of PD (De Lau et al., 2006). The final environmental factor associated with the incidence of PD is exposure to chemicals and toxins, as in farming communities where pesticides are used. However, no one chemical toxin or heavy metal is known as the cause (Victor and Ropper, 2005).

### Medical Management

The “classic triad” signs—tremor at rest, rigidity, and bradykinesia—remain the criterion for medical diagnosis. However, it was well over a century before l-dopa (a precursor to dopamine) was introduced for controlling symptoms. Exelon, a cholinesterase inhibitor, was approved by the FDA in 2006 for use in mild to moderate PD dementia. Pharmacotherapy agents, surgical interventions, and physical therapy are the best adjunctive therapies.

### Medical Nutrition Therapy

The primary nutrition intervention should be to focus on drug-nutrient interactions, especially between dietary protein and l-dopa. Side effects of medications for PD include anorexia, nausea, reduced sense of smell, constipation, and dry mouth. To diminish the gastrointestinal side effects of l-dopa, it should be taken with meals. Avoid foods that contain natural l-dopa such as broad beans (fava beans). For some patients dyskinesia may be reduced by limiting dietary protein at breakfast and lunch and including it in the evening meal. Table 41-11 presents a sample menu for this diet.

Fiber and fluid adequacy lessen constipation, a common concern for persons with PD. Interactions between pyridoxine and aspartame should be considered as well. Pyridoxine has a possible interaction with l-dopa. Decarboxylase, the enzyme required to convert l-dopa to dopamine, depends on pyridoxine. If excessive amounts of the vitamin are present, l-dopa may be metabolized in the periphery and not in the CNS where its therapeutic activity occurs. Therefore vitamin preparations containing pyridoxine should not be taken with doses of l-dopa. In addition, manganese should be carefully monitored to avoid excesses above DRI levels.

The high demand for molecular oxygen, the enrichment of polyunsaturated fatty acids in membrane phospholipids, and the relatively low abundance of antioxidant defense enzymes are all relevant factors (Sun et al., 2008). Antiinflammatory and neuroprotective effects come from phenolic compounds, such as resveratrol from grapes and red wine, curcumin from turmeric, apocynin from *Picrorhiza kurroa*, and epigallocatechin from green tea (Sun et al., 2008). Sufficient intake of vitamin D<sub>3</sub> and ω-3 fatty acids can be suggested.

As the disease progresses, rigidity of the extremities can interfere with the patient’s ability to perform self-feeding. Rigidity interferes with the ability to control the position of the head and trunk, necessary for eating. Eating is slowed; mealtimes can take up to an hour. Simultaneous movements such as those required to handle both a knife and fork

become difficult. Tremor in the arms and hands may make self-feeding of liquids impossible without spilling. Perception and spatial organization can become impaired.

Dysphagia is often a late complication. A large number of patients may be silent aspirators, which affects nutrition status.

Experimental treatment procedures are being tested and reported with increasing frequency. Deep brain penetration,

**CLINICAL SCENARIO**

Clarence is a 74-year-old white man hospitalized for evaluation of dementia progression and recent hearing difficulty. He was diagnosed with Alzheimer's disease 5 years ago and has been taking donepezil (Aricept) and furosemide (Lasix). He lives at home with his 68-year-old Italian wife who is his primary caregiver. Clarence is 5'10" and currently weighs 155 lb. His medical chart indicates that his weight was 170 lb at his last hospital visit 6 months ago, following a fall. Clarence's wife notes that his appetite and hearing seem to have changed and he shows little interest in food at meal times. They don't talk much during home meals and nursing staff have observed his wife helping him eat and suspect some problems with feeding. His wife describes their meals as follows:

**Breakfast:** ½ C oatmeal, ½ C 2% milk, 1 orange ; food is usually consumed while watching the morning news

**Lunch:** ½ C vegetable beef soup, ½ turkey sandwich with white bread, light mayonnaise, lettuce, tomato slice, 10 baby carrots, water

**Supper:** frozen TV dinner (generally small meat serving, vegetable, and starch item;) TV is on in the background

**Nutrition Diagnostic Statement**

Increased energy expenditure

Inadequate fluid intake

Chewing (mastication) difficulty

Self-feeding difficulty

**Nutrition Care Questions**

- What dietary advice do you have for Clarence and his caregiver?
- What types of foods and eating environment are more appropriate for individuals with Alzheimer's disease?
- Develop a plan for monitoring and evaluating Clarence.

other surgical interventions, and efforts with stem cell research continue in hopes that a "cure" is possible.

## CHAPTER 42

Gretchen K. Vannice, MS, RD

# Medical Nutrition Therapy for Psychiatric Conditions

### KEY TERMS

alpha-linolenic acid (ALA)  
arachidonic acid (ARA)  
attention-deficit disorder (ADD)  
**axis I disorders**  
**axis II disorders**  
borderline personality disorder  
*Diagnostic and Statistical Manual, IV (DSM-IV)*

depression  
docosahexaenoic acid (DHA)  
eicosapentaenoic acid (EPA)  
**Minnesota Multiphasic Personality Inventory**  
phytochemicals  
post-partum depression  
post-traumatic stress disorder (PTSD)

Psychiatric disorders (mental illnesses) involve altered brain or nervous system function that may result in altered perception and response to the environment. There are more than 450 million people with mental, neurologic, or behavioral problems throughout the world (World Health Organization, 2010). One in four individuals will suffer some type of mental illness during their lifetime. Indeed, many famous individuals have suffered from mental illnesses in the past (*Focus On: Who Has Suffered from Mental Illness?*)

### CLASSIFICATION

The American Psychiatric Association classifies conditions into two different categories: *Axis I* and *Axis II disorders*. **Axis I disorders** often do not improve without medication. In fact, left unchecked, they can be degenerative and permanently destructive to brain and nervous system tissue. **Axis II disorders** are personality disorders. These disorders are primarily learned behaviors and do not respond to medication, with the possible exception of bipolar disorders, which

may respond to very-long chain ω-3 fatty acids (e.g., fish oil) supplementation.

### Axis I Disorders

The primary Axis I disorders include depression, anxiety disorder, obsessive-compulsive disorder, bipolar disorder, attention-deficit/hyperactivity disorder (ADHD), schizophrenia, and post-traumatic stress disorder (PTSD). The eating disorders (anorexia nervosa, bulimia nervosa, and binge eating disorder) are also classified as Axis I disorders. Thus eating disorders are not merely behavioral issues; they require medical, nutritional, and often pharmacologic treatment in addition to psychotherapy. See Chapter 23. These interventions can be the foundation for successful response to psychotherapy. Nutrition is crucial for the rehabilitation of every mental health issue, not just eating disorders. In 1990 the United States Congress voted to establish the first week of October as Mental Illness Awareness Week, and much progress has been made in the past several decades. Box 42-1 lists psychiatric disorders that can have nutritional implications.

Despite their strong physiologic component, Axis I disorders are diagnosed primarily through behavioral criteria and psychological testing (e.g., the **Minnesota Multiphasic**

Sections of this chapter were written by Monica Woolsey, MS, RD for the previous edition of this text.

## ◎ FOCUS ON

### Who Has Suffered from Mental Illness?

April 20, 1999, Littleton, Colorado: 13 students and 1 teacher were killed, 23 students and 1 teacher wounded in a shootout at Columbine High School.

December 7, 2005, Miami, Florida: A 44-year-old man was shot and killed by air marshals as he ran from a plane claiming he was carrying a bomb.

May 4, 2010, Los Angeles, California: A woman stabs four people at a Target in West Hollywood.

What do these news items have in common? Each of these tragedies involved a person with a mental illness. In addition, in each of the news stories cited, for various reasons, the individual was not using medications to help his or her condition at the time he was involved in the tragic event. Unfortunately, when mental health issues appear in the news, they are often related to tragedies such as these.

What is often overlooked is that some of history's most illustrious and creative individuals accomplished their greatest achievements while also managing the mental chaos, disruption in logical thinking, and hypersensitivity to stress that mental diagnoses can impose on the brain and nervous system. It is to the credit of all of these individuals and to the benefit of all of us who enjoy the outcomes of their labor that they persisted and created in spite of their struggles and emotional turmoil. Famous living and historical figures who had mental illness include Sir Isaac Newton, Ernest Hemingway, Charles Dickens, Michelangelo, Tennessee Williams, Ludwig van Beethoven, Terry Bradshaw, Brooke Shields, President Abraham Lincoln, Winston Churchill, and Vincent van Gogh.

Source: Mental Health Ministries. Accessed 2 November 2010 from [http://www.mentalhealthministries.net/links\\_resources/other\\_resources/famouspeople.pdf](http://www.mentalhealthministries.net/links_resources/other_resources/famouspeople.pdf).

**Personality Inventory).** Because there currently is no definitive diagnostic testing (e.g., blood tests, genetic tests, brain scans) for these disorders, it can be difficult to convince a person with such a diagnosis that he or she has a medical issue requiring treatment. It can also be difficult for friends, family members, and colleagues to understand that challenging behaviors affecting relationships and productivity are sometimes medical or biochemical in origin. For both parties, frustration, shame, and destructive behavior can result from attempting to willfully change behaviors that will not respond to anything less than intensive biologic intervention.

Altered food or eating behaviors can be the first indication that an Axis I disorder exists. For example, a person with obsessive-compulsive disorder may struggle making

## BOX 42-1

### Psychiatric Conditions with Nutritional Implications

- Autism spectrum disorders
- Attention-deficit/hyperactivity disorder
- Bipolar disorder
- Borderline personality disorder
- Dissociative disorders
- Dual diagnosis: mental illness and substance abuse disorder
- Eating disorders
- Major depression
- Obsessive-compulsive disorder
- Panic disorder
- Post-traumatic stress disorder
- Schizoaffective disorder
- Schizophrenia
- Seasonal affective disorder
- Suicide
- Tourette syndrome

choices in grocery stores and restaurants, where a multitude of choices exist. They may seek help from a registered dietitian (RD) for specific direction (e.g., "just tell me what to eat") to lessen the stress that these daily activities can induce. A person with bipolar disorder may alternate between periods of mania and depression. During the manic phase consumption of sugar, caffeine, and large quantities of food can be extreme and during the depression phase food intake may cease completely. These mood fluctuations often manifest as weight fluctuations and can even be misidentified as hypoglycemia. Often the medical comorbidity, not the core mental health diagnosis, is the reason an individual seeks an initial nutrition consultation.

A nutritionist's job is to recognize unusual eating behaviors so that appropriate recommendations for treatment can be made. In general, when an individual seems to be genuinely trying to follow nutrition treatment recommendations or to change behavior, yet seems to be driven to behaviors that counter those intentions, the existence of an Axis I disorder should always be considered and the individual should be evaluated.

### Axis II Disorders

The personality disorders listed in the American Psychological Association, **Diagnostic and Statistical Manual, IV (DSM-IV)** include antisocial, narcissistic, histrionic, schizoid, avoidant, dependent, and borderline behavior. Psychotherapy is required to achieve symptom relief. Axis II disorders differ from Axis I disorders because, to the individual who has an Axis II disorder, the personality change serves an important purpose. A person with low self-esteem or who knows from experience that he or she struggles with interpersonal relationships may develop an Axis II

disorder to prevent abandonment. For a person who does not have alternative communication, conflict resolution or coping skills, the perceived potential loss of that connection to others can be traumatizing. Whereas treating an Axis I disorder can provide great relief and improved well-being, treating an Axis II disorder may actually temporarily *increase* distress and behavioral acting out as treatment progresses.

## Comorbidity

Axis I and Axis II disorders are often comorbid conditions. When an Axis I diagnosis impairs an individual's ability to interact with his or her environment, an Axis II disorder may develop as a coping mechanism. For example, a person with **post-traumatic stress disorder (PTSD)** is likely to be easily overstimulated and fluctuate between periods of intense anxiety and depression. **Borderline personality disorder** is a common condition occurring comorbidly with PTSD. This person with this personality type often engages in extreme behaviors, including hypersexuality, emotional volatility, poor impulse control, manipulative behavior, and suicide attempts to (1) provide an emotional diversion from the physical wear and tear that the PTSD inflicts, and (2) maintain relationships with loved ones the individual perceives might otherwise abandon him or her.

## NUTRITION FOR THE BRAIN AND NERVOUS SYSTEM

One of the most important contributions of nutrition to mental health is the maintenance of the structure and function of the neurons and brain centers coordinating communication within the body and between the body and the environment. See *Pathophysiology and Care Management Algorithm: Psychiatric Disorders*.

### Omega-3 Fatty Acids

Omega-3 ( $\omega$ -3) polyunsaturated fatty acids are preferred fatty acids in the brain and nervous system. From conception through maturity, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA)  $\omega$ -3 fatty acids make unique, important, and irreplaceable contributions to overall brain and nervous system functioning. Clinical research has shown effective and promising roles for EPA and DHA  $\omega$ -3 fats in various psychiatric conditions.

**Alpha-linolenic acid (ALA)**, another  $\omega$ -3 fat with a chain length of 18 carbons and 3 double bonds (18:3  $\omega$ -3), is found in the oil of some seeds (e.g., flax, chia, sunflower) and some nuts (walnuts are the best source). **Eicosapentaenoic acid (EPA)** is a 20-carbon  $\omega$ -3 fatty acid with 5 double bonds (20:5  $\omega$ -3), and **docosahexaenoic acid (DHA)** is a 22-carbon fatty acid with 6 double bonds (22:6  $\omega$ -3). EPA and DHA occur naturally in fatty fish and seafood.

### Conversion Factors

ALA serves as a precursor for EPA and DHA. Research has shown that conversion of ALA to EPA and DHA in humans is low: conversion of ALA to EPA is approximately 5% to 10%, and conversion of ALA to DHA is even lower (<3%).

Health status and other nutritional factors appear to influence conversion rates. There are also genetic variations in conversion (e.g., production of delta-6 desaturase enzyme), and recent studies have suggested possible differences in conversion rates between vegetarians and carnivores. Individuals with mental health conditions often have compromised nutritional intake or eating habits. Most nutrition and mental health experts do not recommend reliance on ALA as a source of EPA or DHA (Davis and Kris-Etherton, 2003; Harris et al, 2009; Kris-Etherton and Innis, 2007).

### Omega-3s, Omega-6s and Mental Health

EPA works in balance with **arachidonic acid (ARA)**, a 20-carbon  $\omega$ -6 fatty acid with 4 double bonds (20:4  $\omega$ -6). ARA and EPA are eicosanoids, that is, precursors to prostaglandins, thromboxanes, and leukotrienes, which are involved with inflammation, vasoconstriction, and a multitude of metabolic regulations. Although specific mechanisms remain unclear, clinical research has shown the importance of sufficient EPA intake for general mental health, and particularly for nutrition support in conditions such as depression, suicide ideation, and homicide. In general, EPA works better when ingested with DHA. They also occur together naturally in foods.

DHA is preferred and selectively stored in brain and nerve cells. Similar to EPA, DHA is involved with metabolic regulation. DHA is required for normal brain growth, development, and maturation. DHA is involved with neurotransmission (how brain cells communicate with each other), lipid messaging, genetic expression, and cell membrane synthesis. DHA also provides vital structural contributions; DHA is concentrated in the phospholipids of brain cell membranes. Box 42-2 lists conditions in which DHA and EPA play a role.

### Diet Is First

Although deep-sea oily fish such as salmon and tuna contain more EPA and DHA per serving, all fish and seafood contain

### BOX 42-2

#### Some Conditions for Which EPA and DHA have Benefit

- Anxiety disorder
- Attention-deficit/hyperactivity disorder
- Autism
- Bipolar disorders
- Depression
- Dyspraxia
- Eating disorders
- Postpartum depression
- Schizophrenia
- Suicide ideation

*DHA*, Docosahexaenoic acid; *EPA*, eicosapentaenoic acid.

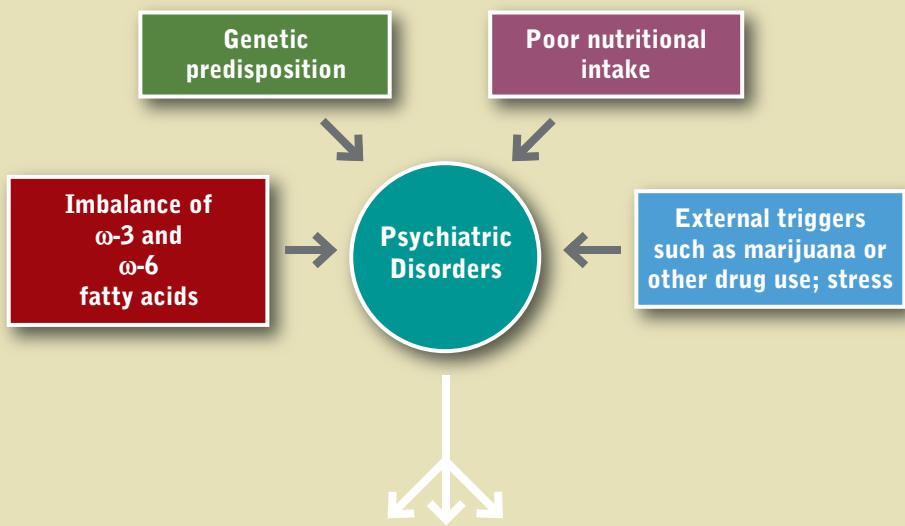

## PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

### Psychiatric Disorders

ETIOLOGY

PATHOPHYSIOLOGY

MANAGEMENT

#### Clinical Findings

- ↑ or ↓ serum cholesterol
- Elevated serum triglycerides
- ↑ C-reactive protein
- Blood pressure changes
- Low HDL-cholesterol
- Metabolic syndrome?
- Serum glucose (high or low)

#### Nutrition Assessment

- BMI evaluation  
Dietary assessment for:
- Fatty acids
  - Antioxidants and phytochemicals
  - Excessive processed foods
  - Excessive refined carbohydrates
- Assess for weight changes

#### Neurochemical Changes

- Production of fewer neurotransmitters
- Altered neurotransmitter levels
- Changes in neurotransmitter receptor density

#### Medical Management

- Antipsychotics
- Antidepressants
- Cardiac medications

#### Nutrition Management

- TLC diet if lipids elevated
- DASH dietary pattern
- Increase ω-3 rich foods and/or supplement
- High fruit and vegetable intake for phytochemicals and antioxidants
- Weight reduction if needed

some ω-3 in varying amounts. Sardines, for example, are an excellent choice, whereas tilapia is low in ω-3 fatty acids. There are additional benefits of consuming fish in the diet; fish provides lean protein and trace minerals and can displace other less nutritious food choices. However, the white fish used in processed food fish fillets is lower in ω-3; and because of the added batter and frying, the caloric contribution of ω-3s may be less than the other fat calories in these convenience foods. See [Appendix 40](#).

#### During Pregnancy and Lactation

Experts recommend that pregnant women consume at least 200–300 mg DHA during pregnancy for proper infant development ([Koletzko, 2007](#)). The role of DHA and EPA in pregnancy and lactation is discussed in [Chapter 16](#).

Up to 10% of pregnant women can experience depression, and there is considerable interest in finding effective alternatives to prescription medication. Several pilot trials using EPA and DHA from fish oil have been conducted

in depressed pregnant women and women with **postpartum depression**. One dose-ranging study reported measurable improvements in women who consumed as little as 500 mg of combined EPA and DHA. Experts have also recently suggested that a daily intake of 900 mg DHA during pregnancy may be necessary to support both infant and maternal needs. A landmark study that followed more than 9000 pregnant women and their children for 8 years reported lower intelligence quotient and social development in the children of those women who consumed less than 12 ounces of fish a week while pregnant. In other words, the children of the women who ate fish two or more times a week during their pregnancy fared better emotionally and mentally in their youth (Freeman et al, 2006a, 2006b; Hibbeln et al, 2007b; Hibbeln and Davis, 2009).

### **During Infancy**

Breast milk contains EPA and DHA  $\omega$ -3 and ARA  $\omega$ -6. In 2002 the United States began fortifying infant formula with DHA and ARA. Because DHA has an identified role in infant development (brain, eyes, central nervous system), experts agree that DHA should be considered an essential nutrient in infancy, particularly among preterm infants. DHA accumulation in the brain begins in utero and continues into adolescence. It is important to remember that humans (including infants) cannot synthesize  $\omega$ -3 fatty acids; the amount taken in depends on the feeding source. Infants can convert EPA and DHA from ALA, but again conversion of ALA to DHA has been shown to be inadequate for infant needs. A precise role for  $\omega$ -3s in neurologic conditions, such as autism spectrum disorder, is currently being considered but remains unclear. See Chapter 45.

### **During Childhood**

Depression among children is increasing. The few clinical trials conducted in depressed children have shown significant benefit from EPA and DHA fish oil supplementation. At the same time, the few studies measuring consumption of EPA and DHA in children report very low average intakes.

Most clinical trials using EPA and DHA from fish oil supplements in children with **attention-deficit disorder (ADD)** or ADHD have reported benefit, but not all. The difference in findings may be due to many variables, including study design, dose, age of supplementation, the background diet, genetics, and teacher or family dynamics. However, it has been shown that children with ADD, ADHD, behavior problems, or who are overweight tend to have lower levels of EPA and DHA in their blood (Antalis et al, 2006; Richardson, 2000, 2006). Box 42-3 lists questions about fatty acids and a person's early feeding history that may be useful in a nutrition assessment.

### **During Adulthood**

According to the World Health Organization, major depression is the leading cause of disability around the world. **Depression** is a mental health condition; diagnosis and treatment by a mental health professional is recommended. A significant number of depressed individuals feel ashamed

### **BOX 42-3**

#### **Questionnaire: Early Feeding History and Fatty Acid Intake**

- Were you born at term?
- If you were born early, how early?
- Did your premature birth affect how and what you were fed?
- Did your mother have prolonged postpartum depression after you were born? If yes, how did this influence your feeding?
- Were you nursed or bottle-fed? For how long? In what country? If formula-fed, which formula?
- How many children did your mother have and nurse and for how long each time?
- Where are you in the rank of your siblings? (Essential fatty acid availability may decrease with successive pregnancies).
- Women: How many children have you nursed? For how long?

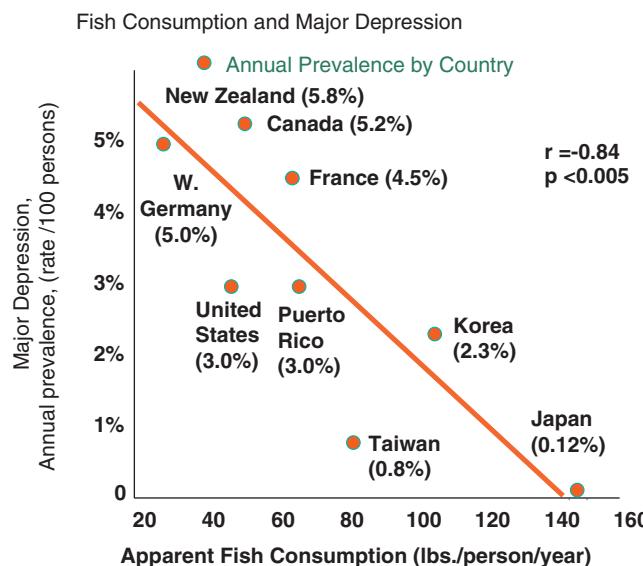

and do not seek treatment. Those who suffer from depression tend to report lower quality of life, social impairment, and problems in the workplace. Data from the National Health and Nutrition Examination Survey suggests that more than 1 in 20 adults in the United States are experiencing depression, and it is more common among women and the poor. Depression is often associated with poor health and higher health care costs.

Epidemiologic research has identified associations between lower seafood consumption and increased rates of depression around the world. See Fig. 42-1. Dozens of clinical studies using EPA and DHA  $\omega$ -3 supplements for depression have been conducted, and results are mixed but generally positive (Martins, 2009). Questions remain regarding the dose of  $\omega$ -3s, the form, and the duration of supplementation. In 2011 more than 30 clinical trials are investigating the relationship between  $\omega$ -3s and depression. Omega-3s are often provided in conjunction with antidepressant medication and usually show additive benefit (Freeman et al, 2006a; Jazayeri et al, 2008).

Increases in homicide occurrence have been associated with less seafood consumption. This finding led to an article in the *New York Times* entitled “Does Eating Salmon Lower the Murder Rate?” (Mihm, 2006). When EPA and DHA  $\omega$ -3s and multivitamins were given to prison inmates, anti-social behavior, including violence, fell significantly, compared with those on placebo. In another study, teens who had previously attempted suicide made fewer suicide attempts when given EPA and DHA (Hallahan et al, 2007; Hibbeln, 2001, 2007a).

### **During the Aging Years**

Omega-3 fatty acids are also considered important in maintaining cognitive function with age. Research suggests

Hibbeln, *The Lancet* 1998;351:1213

**FIGURE 42-1** Fish Consumption and Major Depression

This inverse relationship between the amount of fish consumed by a population and the incidence of depression in that population is thought to be related to amount of  $\omega$ -3 fats contributed by fish in the diet, and resulting body and brain tissue levels of  $\omega$ -3 fats. (*Hibbeln JR: Fish consumption and major depression, Lancet* 351:1213, 1998.)

that individuals who consume more fish and seafood during their lifetimes have better cognitive function as they age. Higher blood levels of DHA have been associated with better cognitive function in middle adulthood. Some studies have shown that eating fish or supplementing with EPA and DHA  $\omega$ -3s improves cognition (e.g., delays cognitive decline) and the onset of dementia, but not all studies report positive findings and questions remain, including the role of genetics in risk factors for onset of cognitive difficulties. Researchers and dietitians question if EPA and DHA  $\omega$ -3s have a greater effect in prevention or intervention for mental health (Dangour et al, 2010; Muldoon et al, 2010; Vannice, 2005; Whalley et al, 2004). Neurologic disorders are discussed in Chapter 41.

Although much focus is on DHA, it is interesting to note that research has generally shown that consuming both EPA and DHA, but more EPA relative to DHA is necessary for clinical benefit in many psychiatric conditions. To date clinical intervention studies in mental health using DHA alone have been generally disappointing. Researchers are actively seeking answers. Freeman et al, 2006; Marangell et al, 2003, Martins, 2009.

The American Dietetic Association recommends that children and adults eat fish at least twice a week. A minimum intake of 500 mg EPA and DHA is recommended for adults (Kris-Etherton and Innis, 2007). The International Society for the Study of Fatty Acids and Lipids also recommends a daily minimum of 500 mg combined of EPA and DHA (Cunnane, 2004). American Psychiatric Association recommendations for  $\omega$ -3 intake are shown in Table 42-1.

**TABLE 42-1**

**American Psychiatric Association Recommendations for Omega-3 Intake**

Who	Recommendation
All adults	Eat fish two or more times per week.
Individuals with mood, impulse-control, or psychotic disorders	Consume 1 g (1000 mg) EPA and DHA per day.
Patients with mood disorders	Use a supplement providing 1-9 g of EPA and DHA. Use of more than 3 g/day should be monitored by a physician.

DHA, Docosahexaenoic acid; EPA, eicosapentaenoic acid.

## Omega-3 Supplements

As supplements, EPA and DHA  $\omega$ -3 fatty acids are available from fish oil and cod liver oil. Other marine sources, such as krill and calamari, are coming to the market. An algal (vegetarian) source of DHA is also available. Omega-3 supplements are best absorbed when consumed with a fat-containing meal or snack. This practice also improves patient compliance, particularly with higher doses. Better  $\omega$ -3 supplements include an antioxidant, such as vitamin E, in the formula. The purpose of adding an antioxidant is to stabilize and preserve the long-chain polyunsaturated fats. Fortification of foods with  $\omega$ -3s is increasing, and as always, reading the label is imperative to know the form and dose of  $\omega$ -3. Genetically modified forms of EPA and DHA are also coming to the market for use in fortified foods and supplements (Vannice, 2010). See *Focus On: Genetically Modified (GM) Foods*, in Chapter 27.

## Vitamin D

Vitamin D affects hundreds of genes in the human body and is recognized as an important nutrient for brain health as well as for bone and skeletal health. Because vitamin D can be synthesized from sunlight, adequate sun exposure or vitamin D<sub>3</sub> intake can help maintain mental health. Clinical research has associated vitamin D deficiency with the presence of an active mood disorder, with aspects of cognitive disorder as well as increased risk for both major and minor depression in older adults (Hoogendoijk et al, 2008; Stewart et al, 2010; Wilkins et al 2006).

In November 2010 the Institute of Medicine (IOM) of the National Academies published new dietary reference intakes for vitamin D. Focusing on vitamin D and physical health, specifically bone health, the IOM report established a recommended dietary allowance (RDA) of 600 IU/day of vitamin D, an increase of 50% from 1997 (Institute of

(Medicine, 2010). The tolerable upper limit was increased to 4000 IU/day.

Serum levels of vitamin D are most often tested by assessing circulating levels of 25(OH)D, which is the combined product of skin synthesis from sun exposure and dietary sources (Calvo et al, 2005). Currently, no official agreement has been reached regarding blood levels of 25(OH)D that indicate deficiency, insufficiency, and sufficiency of vitamin D. Other biomarkers of nutritional vitamin D status include parathyroid hormone levels, intestinal calcium absorption, insulin sensitivity, beta cell function, and innate immune function.

The best sources of vitamin D are exposure to sunlight, foods such as oily fish and egg yolks, and fortified foods, such as cow, soy or other fortified milks, and cereals. Due to recent changes in lifestyle such as more time indoors and more use of sunscreens to protect against skin cancer, many people do not receive adequate exposure to sunlight. Similarly, many people do not eat egg yolks, oily fish, or fortified foods in sufficient quantity to meet the RDA for vitamin D. Therefore recommending supplements or ensuring regular consumption of fortified foods may be warranted.

## B-Complex Vitamins

The B-complex vitamins are known for having an effect on neurologic and brain health and sufficient intake is important for individuals with psychiatric disorders. Recent human studies have identified genetic alterations that alter the production and function of serotonin, dopamine, and other neurotransmitters. These alterations may be identified by various biochemical or deoxyribonucleic acid (DNA) testing. For example, the methylenetetrahydrofolate reductase (MTHFR) test can reveal alleles (C > T and A > C) that decrease production of serotonin and dopamine, as well as increase homocysteine retention. Clients with these genetic SNPs (see Chapter 5) usually require folate supplementation in a methylated form. A methylmalonic acid test can reveal whether B<sub>12</sub> levels are sufficient to maintain low serum homocysteine levels. See Chapters 3, 8, and 33 for further discussion of the B vitamins and brain function.

The best sources of folate are brewer's yeast, mushrooms, spinach, broccoli, brussels sprouts, asparagus, kale and other greens, legumes, liver, and orange juice. Vitamin B<sub>12</sub> is found in animal sources only, such as beef, liver, clams, oysters, crab, tuna, and halibut. Thus, vegans must choose foods and supplements wisely. Pyridoxine (B<sub>6</sub>) is found in beef liver, oatmeal, bananas, chicken, potatoes, avocado, sunflower seeds, brewer's yeast, halibut, pork, and brown rice.

## Phytochemicals

New research suggests that plant-based foods rich in the bioactive chemicals, **phytochemicals**, make important nutritional and biochemical contributions to normal brain function and mental health. Foods such as berries, citrus fruits, green tea and some spices contain phytochemicals, as well as essential vitamins and minerals. The phytochemicals

showing the most promise are 3 sub-classes of flavonoids: flavanols, anthocyanins and flavanones. These phytochemicals have antioxidant activity, but their more important contributions may be protecting and preserving brain cell structure and metabolism through a complex cascade of cellular mechanisms, including signaling, transcription, phosphorylation and gene expression (Williams et al, 2004; Dashwood, 2008; Spencer, 2010).

There is evidence that other plant-based foods have nutritional and possibly pharmacological effects in the brain, but the mechanisms are yet to be elucidated. These foods appear to impact brain health through antioxidant, anti-inflammatory and nutrigenomic influences, and more mechanisms are plausible. Examples of these foods include onion, ginger, tumeric, oregano, sage, rosemary and garlic. This is an exciting area of research to watch in the 21st century (Jellin, 2011).

A summary of flavonoids and nutrients that support healthy brain and nervous system can be found in Table 42-2.

## WEIGHT MANAGEMENT

Managing weight, eating behaviors and diet can be challenging for psychiatric patients. Depression and other mental health conditions are known to affect nutrition choices, interpersonal relationships, and lifestyle habits such as

**TABLE 42-2**

### Phytochemicals and Nutrients that Support Brain and Mental Health

#### Flavonoid-Rich Foods

Apples
Berries, particularly red, blue, and purple
Chocolate
Citrus fruits, such as oranges, grapefruit and lemons
Grapes and grape juice
Teas, including green, black, white, and oolong

α-Lipoic acid
Choline
Docosahexaenoic acid
Eicosapentaenoic acid
Folate
Glutathione
Selenium
Thiamin
Vitamin A
Vitamin B <sub>6</sub>
Vitamin B <sub>12</sub>
Vitamin C
Vitamin D
Vitamin E

smoking, drinking, and self-care and each of these factors influence food choices and cooking practices. Individuals with psychiatric disorders who are taking psychotropic medicines may experience rapid or excessive weight gain. In fact, a commonly known side-effect of anti-depressant medications is weight gain, and many patients cite this reason to avoid or cease use of their medication. Depressed individuals can also experience loss of appetite and unintentional weight loss or anorectic behavior (Freeman et al., 2006; Jensen, 2008; Murphy et al., 2009).

Being proactive with patients is important. Keep in mind that eating behavior, appetite, focus, concentration, and even the circadian rhythm which affects the sleep/wake cycle can be altered. Individuals may lose or gain interest in food, shopping, and cooking, which affects their families as well as themselves. Working with patients to strategize healthy food choices, to practice supportive eating behaviors and meal planning is valuable. Knowing that one's loved ones are cared for through a difficult period can be rewarding and psychologically uplifting. Encouraging regular physical activity and eating plans that support healthy weight and alleviate stress in the home and workplace is helpful (Gouin et al., 2010; Kiecolt-Glaser, 2010).

## ADDICTION AND SUBSTANCE ABUSE RECOVERY

Addiction is a chronic brain disorder that involves compulsive and relapsing behavior, with biochemical, psychological, and social vulnerabilities. A variety of behavioral and psychological anomalies result from ingestion of or exposure to a drug of abuse, medication, or toxin. The master "pleasure" molecule of addiction is dopamine; it is triggered by heroin, amphetamines, marijuana, alcohol, nicotine, and caffeine (Escott-Stump, 2012). In addition, poor diet and stress enhance the problems of the addicted individual and family members.

Alcohol dependence is a public health concern throughout the world. Event-related brain oscillations are seen, along with inherited neuroelectric deficits; for example, the serotonin receptor gene HTR7 is part of the biologic basis of alcohol dependence (Zlojutro et al., 2010). The addictive personality type is often perfectionistic and prone to depression; antidepressant medications may be useful for some individuals.

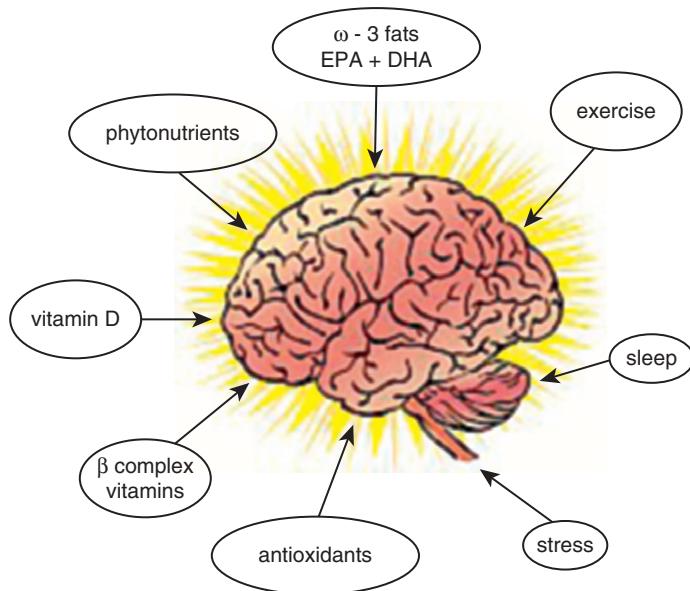

Eating disorders and substance abuse are similar; many clients have both. Eating disorders can arise from gene-environment interactions that alter genetic expression via epigenetic processes (Campbell et al., 2010). In most psychiatric disorders, either increased or decreased changes in appetite occur. It is important to be aware of the types of malnutrition and counseling techniques appropriate for this population. Counseling should include tips such as how a proper, nutritious diet can reduce cravings; how to choose a brain-healthy diet; maintaining physical activity; choosing nutrient-rich snacks; stress management; and tracking positive changes and successes (see Chapter 23).

## NUTRITION INTERVENTIONS

The primary responsibility of a dietitian working with individuals who have a mental health diagnosis is to impart information and support for eating choices that minimize the negative effects of these illnesses on the client and their affected loved ones. Therapy for behavioral issues is primarily the responsibility of the psychotherapy team. Common nutrition diagnoses in this population may include:

- Deficit of food and nutrition knowledge
- Harmful food and nutrition attitudes and beliefs
- Poor food choices
- Nutrient deficiencies
- Imbalance of fats from foods
- Excessive carbohydrate intake
- Excessive intake of processed and refined foods
- Altered nutrition-related laboratory values
- Excessive or inadequate oral food and beverage intake
- Underweight, overweight or obesity
- Food-medication interactions

Individuals who have a psychiatric condition may not adapt readily to the fluctuations of life and changes in diet and lifestyle can exacerbate anxiety or depression. When working with the mentally ill, the dietitian should incorporate varying responses to diet, environment, genetics, behavior and stress and offer support and strategies to these individuals. See Fig. 42-2. For example, a primary goal of "behavioral change" in nutrition counseling is not usually easily embraced by members of this population. Although the long-term outcome of healthy food and lifestyle change is certainly positive, a person with a psychiatric condition, regardless of intelligence and life-stage, may find *any* change (e.g., food

**FIGURE 42-2** Brain function is affected by many more nutrients and lifestyle factors than previously thought, and research is rapidly revealing new connections. (© 2011 Photos.com a division of Getty Images. All rights reserved.)

choices, relationships, or any life situation) overwhelming or even frightening. However, even small improvements in nutritional status can lead to meaningful results. And a positive experience with a dietitian can build a foundation and motivation to attempt other positive changes long after nutrition counseling is finished.

For dietitians working in psychiatric units, suicide precautions are often needed. Therefore, those meals require

special attention to prevent giving patients anything that they could use to do harm to themselves or others. Plastic utensils and paper goods may be a necessary precaution. A balanced, nutritious diet rich in  $\omega$ -3 fatty acids and plant-based foods should be made available. Table 42-3 gives more specific guidance about nutrition in other psychiatric conditions.

*Text continued on p. 968*

**TABLE 42-3**

**Nutrition for Specific Psychiatric Conditions**

Mental Disorder	Explanation	Relevance to Nutrition
Acute stress disorder or posttraumatic stress disorder	Development of anxiety and dissociative and other symptoms within 1 month following exposure to an extremely traumatic event; the symptoms may include reexperiencing the event, nightmares, and avoidance of trauma-related stimuli.	May increase or decrease appetite. Overall nutrition status may decline, or obesity may result.
Adjustment disorder	Maladaptive reaction to identifiable stressful life events.	May increase or decrease appetite. Overall nutrition status may decline, or obesity may result.
Amnestic disorder	Mental disorder characterized by acquired impairment in the ability to learn and recall new information, sometimes accompanied by inability to recall previously learned information, and not coupled with dementia or delirium.	Impaired ability to retain new information from nutrition counseling.
Anxiety disorders	A group of mental disorders in which anxiety and avoidance behavior predominate, including panic disorder, agoraphobia, specific phobias, social phobia, obsessive-compulsive disorder, posttraumatic stress disorder, acute stress disorder, and generalized anxiety disorder.	May increase or decrease appetite. Overall nutrition status may decline, or obesity may result. May respond to increased intake of $\omega$ -3 fats to 1-3 g/day.
Attention deficit disorder and attention-deficit/hyperactivity disorder	Mental disorder characterized by inattention (such as distractibility, forgetfulness, not finishing tasks, and not appearing to listen), hyperactivity and impulsivity (such as fidgeting and squirming, difficulty in remaining seated, excessive running or climbing, feelings of restlessness, difficulty awaiting one's turn, interrupting others, and excessive talking) or both types of behavior	Impaired ability to retain and use new information after nutrition counseling. May respond to increased intake of $\omega$ -3 fats to 1-3 g/day.
Autistic disorder	Severe pervasive developmental disorder with onset usually before 3 years of age and a biologic basis related to neurologic or neurophysiologic factors. Characterized by qualitative impairment in reciprocal social interaction (e.g., lack of awareness of the existence of feelings of others, failure to seek comfort at times of distress, lack of imitation), verbal and nonverbal communication, and capacity for symbolic play and by restricted and unusual repertoire of activities and interests.	May affect appetite, with increased needs common. Overall nutrition status may decline. May respond to increased intake of $\omega$ -3 fats, especially DHA, to 1-3 g/day. Gluten-free, casein-free, or soy-free diet may be useful.
Binge eating disorder	An eating disorder characterized by repeated episodes of binge eating, as in bulimia nervosa, but not followed by inappropriate compensatory behavior such as purging, fasting, or excessive exercise.	May affect nutrition status; health may decline or obesity may result.

**TABLE 42-3****Nutrition for Specific Psychiatric Conditions—cont'd**

<b>Mental Disorder</b>	<b>Explanation</b>	<b>Relevance to Nutrition</b>
Bipolar disorders	Mood disorders characterized by a history of manic, mixed, or hypomanic episodes, usually with concurrent or previous history of one or more major depressive episodes.	May increase or decrease appetite. Overall nutrition status may decline, or obesity may result. May respond to increased intake of ω-3 fats to 1-3 g/day preferably in combination with standard mood stabilizers.
Body dysmorphic disorder	A mental disorder in which a normal-appearing person is either preoccupied with some imagined defect in appearance or is overly concerned about some very slight physical anomaly.	Likely to cause altered eating habits with potential for decline in intake. May lead to eating disorder. May be prone to food fads or use of herbs or steroids.
Catatonia	Immobilization caused by the physiologic effects of a general medical condition.	May decrease appetite. Overall nutrition status may decline.
Childhood disintegrative disorder	Pervasive developmental disorder characterized by marked regression in a variety of skills, including language, social skills or adaptive behavior, play, bowel or bladder control, and motor skills after at least 2, but less than 10 years of apparently normal development.	May increase or decrease appetite. Overall nutrition status may decline; or obesity may result.
Conduct disorder	A type of disruptive behavior disorder of childhood and adolescence characterized by a persistent pattern of conduct in which rights of others or age-appropriate societal norms or rules are violated.	No specific nutritional challenges except that mealtimes may be disrupted.
Conversion disorder	Mental disorder characterized by conversion symptoms (loss or alteration of voluntary motor or sensory functioning suggesting physical illness, such as seizures, paralysis, dyskinesia, anesthesia, blindness, or aphonia) having no demonstrable physiologic basis.	May increase or decrease appetite. Overall nutritional status may decline or obesity may result.
Delusional disorder	Mental disorder marked by well-organized, logically consistent delusions, but lacking other psychotic symptoms. Most functioning is not markedly impaired, the criteria for schizophrenia are not met; symptoms of a major mood disorder are present only briefly, but delusional disorder may coexist with other psychiatric conditions.	May increase or decrease appetite. Overall nutrition status may decline, or obesity may result.
Depersonalization disorder	Dissociative disorder characterized by one or more severe episodes of depersonalization (feelings of unreality and strangeness in one's perception of self or one's body image) not caused by another mental disorder such as schizophrenia. The perception of reality remains intact; patients are aware of their incapacitation. Episodes are usually accompanied by dizziness, anxiety, or fears of going insane.	May increase or decrease appetite. An eating disorder or obesity can result; overall nutrition status may decline.
Depressive disorders	Mood disorders, such as major depressive disorder, dysthymia, or minor depression, in which depression is unaccompanied by manic or hypomanic episodes.	May increase or decrease appetite. Nutrition status may decline. May respond to increased intake of ω-3 fats to 1-3 g/day.

*Continued*

**TABLE 42-3****Nutrition for Specific Psychiatric Conditions—cont'd**

Mental Disorder	Explanation	Relevance to Nutrition
Dissociative disorders	Mental disorders characterized by sudden, temporary alterations in identity, memory, or consciousness, segregating normally integrated memories or parts of the personality from the dominant identity of the individual.	May increase or decrease appetite. Overall nutrition status may decline, or obesity may result.
Dissociative identity disorder	A disorder characterized by the existence in an individual of two or more distinct personalities, each having unique memories, characteristic behavior, and social relationships. Also referred to as <i>multiple personality disorder</i> .	May increase or decrease appetite. Overall nutrition status may decline, or obesity may result.
Dysthymic disorder	Mood disorder characterized by depressed feeling (sad, blue, low), loss of interest or pleasure in one's usual activities, and by at least some of the following: altered appetite, disturbed sleep patterns, lack of energy, low self-esteem, poor concentration or decision-making skills, and feelings of hopelessness. Symptoms have persisted 2 years but are not severe enough to meet the criteria for major depressive disorder.	May increase or decrease appetite. Overall nutrition status may decline, or obesity may result. May coexist with an eating disorder. May respond to increased intake of ω-3 fats to 1-3 g/day.
Eating disorders	Any of several disorders in which abnormal feeding habits are associated with psychological factors; in DSM-IV these include anorexia nervosa, bulimia nervosa, pica and rumination disorder.	Overall nutrition status may decline, or obesity may result, depending on the specific condition. May respond to increased intake of ω-3 fats to 1-3 g/day. See Chapter 23.
Generalized anxiety disorder	Disorder characterized by the presence of excessive, uncontrollable anxiety and worry about two or more life circumstances for 6 months or longer, accompanied by some combination of restlessness, fatigue, muscle tension, irritability, disturbed concentration or sleep, and somatic symptoms.	May increase or decrease appetite. Overall nutrition status may decline, or obesity may result. May coexist with an eating disorder. May benefit from increased intake of ω-3 fats, especially DHA, 1-3 g/day.
Impulse control disorders	Group of mental disorders characterized by repeated failure to resist an impulse to perform some act harmful to oneself or others.	May increase or decrease appetite. Overall nutrition status may decline, but more likely obesity may result.
Motor skills disorder	Any disorder characterized by inadequate development of motor coordination severe enough to limit locomotion or restrict the ability to perform tasks, schoolwork, or other activities.	No specific nutritional changes, but may have difficulty preparing food.
Obsessive-compulsive disorder	Anxiety disorder characterized by recurrent obsessions (often about fear of contamination, disease, or other harm or punishment) or compulsions that are severe enough to interfere significantly with personal or social functioning. Performing compulsive rituals may release tension temporarily, and resisting them causes increased tension.	May increase or decrease appetite. May be avoidance of specific foods or food groups. Overall nutrition status may decline, or obesity may result.

**TABLE 42-3****Nutrition for Specific Psychiatric Conditions—cont'd**

Mental Disorder	Explanation	Relevance to Nutrition
Oppositional defiant disorder	A type of disruptive behavior disorder characterized by a recurrent pattern of defiant, hostile, disobedient, and negativistic behavior directed toward those in authority, including such actions such as defying the requests or rules of adults, deliberately annoying others, arguing, spitefulness, and vindictiveness that occur much more frequently than would be expected on the basis of age and developmental stage.	May increase or decrease appetite. Overall nutrition status may decline, or obesity may result. Mealtimes and thus quality of nutritional intake may be disrupted.
Pain disorder	A somatoform disorder characterized by a chief complaint of severe chronic pain that causes substantial distress or impairment in functioning; the pain is neither feigned nor intentionally produced, and psychological factors appear to play a major role in its onset, severity, exacerbation, or maintenance.	May increase or decrease appetite. Overall nutrition status may decline, or obesity may result. May benefit from increased intake of $\omega$ -3 fats, especially EPA, for their inflammatory effect, 1-3 g/day.
Panic disorder	Anxiety disorder characterized by recurrent panic (anxiety) attacks, episodes of intense apprehension; fear or terror associated with somatic symptoms such as dyspnea, palpitations, dizziness, vertigo, faintness, or shakiness, and with psychological symptoms such as feelings of unreality or fears of dying, going crazy, or losing control. There is usually chronic nervousness and tension between attacks; often, but not always associated with agoraphobia.	May increase or decrease appetite. Food may be used to soothe. Overall nutrition status may decline, or obesity may result.
Personality disorders	Mental disorders characterized by enduring, inflexible, and maladaptive personality traits that deviate markedly from cultural expectations; are self-perpetuating; pervade a broad range of situations, and either generate subjective distress or result in significant impairments in social, occupational, or other functioning. Onset in adolescence or early adulthood.	May increase or decrease appetite. Overall nutrition status may decline, or obesity may result. May respond to increased intake of $\omega$ -3 fats to 1-3 g/day.
Pervasive developmental disorders	Group of disorders characterized by impairment of development in multiple areas, including the acquisition of reciprocal social interaction, verbal and nonverbal communication skills, and imaginative activity, and by stereotyped interests and behaviors. Included are autism, Rett syndrome, childhood disintegrative disorder, and Asperger syndrome.	Comprehension of information shared during nutrition counseling may be affected. Autism and Asperger syndrome may benefit from dietary and nutrition changes.
Premenstrual dysphoric disorder	Premenstrual syndrome viewed as a psychiatric disorder. Often referred to as <i>PMS</i> .	May increase or decrease appetite. Overall nutrition status may decline, or obesity may result. May benefit from increasing intake of $\omega$ -3 fats to 1-3 g/day.
Rumination disorder	Eating disorder seen in infants younger than 1 year of age; after a period of normal eating habits, the child begins excessive regurgitation and rechewing of food, which is then ejected from the mouth or reswallowed.	If untreated, death from malnutrition may occur. May require enteral or parenteral nutrition.

*Continued*

**TABLE 42-3****Nutrition for Specific Psychiatric Conditions—cont'd**

Mental Disorder	Explanation	Relevance to Nutrition
Schizoaffective disorder	A mental disorder in which a major depressive episode, manic episode, or mixed episode occurs along with prominent psychotic symptoms characteristic of schizophrenia. Symptoms of the mood disorder are present for a substantial portion of the illness, and the disturbance is not the result of the effects of a psychoactive substance.	May increase or decrease appetite. Overall nutrition status may decline, or obesity may result. May respond to increased intake of ω-3 fats to 1–3 g/day, preferably in combination with antipsychotic drugs.
Seasonal affective disorder	A cyclic mood disorder characterized by depression, extreme lethargy, increased need for sleep, hyperphagia, and carbohydrate craving. It intensifies most commonly in winter months and is hypothesized to be related to melatonin levels. In DSM-IV terminology called “mood disorder with seasonal pattern.” Often referred to as “winter blues” in common parlance.	May increase or decrease appetite. Overall nutrition status may decline, or obesity may result. May respond to increasing ω-3 fat intake to 1–3 g/day. May benefit from increasing protein intake to balance blood sugar levels.
Sleep disorder	Chronic disorders involving sleep. Primary sleep disorders comprise dyssomnias and parasomnias. Causes of secondary sleep disorders may include a general medical condition, mental disorder, or psychoactive substance.	May affect appetite, with increased intake common; night eating syndrome may present. Obesity may result.

## CLINICAL SCENARIO

Nels is a 20-year-old white man who was recently admitted to the adult psychiatric unit of your hospital. He has exhibited signs of psychosis, and his medical record indicates a family history of schizophrenia, diabetes, and bipolar disorder. He has been prescribed aripiprazole and bupropion; he is becoming more alert. His fasting blood glucose is normal at 100 mg/dL, but his serum low-density lipoprotein cholesterol is low at 70 mg/dL. His diet has been poor lately, and he has been consuming mostly snack foods and sweetened carbonated beverages. He seldom eats fish and eats fewer than three fruits and vegetables weekly.

### Nutrition Diagnostic Statements

1. Inadequate intake of food fats (i.e., ω-3 fatty acids) related to poor diet as evidenced by low serum cholesterol and psychiatric symptoms.

2. Inadequate bioactive substance intake related to antioxidants and phytochemicals as evidenced by intake of fewer than three fruits and vegetables weekly.

### Nutrition Care Questions

1. What information will you need to assess his nutritional history and patterns more thoroughly?
2. What dietary components will you suggest for Nels?
3. What are the nutritional side effects of the medications he is taking?
4. What long-term nutrition care will he need?

## Pediatric Specialties

The unique, special roles of nutrition in the pediatric population cannot be underestimated. Pediatricians, nurses, and dietitians all recognize that unusual feeding problems or disorders can negatively influence growth and health, especially in the very young. This section addresses the categories affecting the nutritional intake and growth velocity of infants and children. In some cases, adolescents are mentioned if relevant, but most of this section considers younger patients.

Whether in neonatal units, in hospital pediatric units, in out-patient clinics, in long-term care units, or in home care, children need to grow as well as cope with genetic or acquired disorders. More than ever, nutrition care in this specialty arena requires an understanding of the biochemical, physiological, social, and economic challenges that our youngest citizens face.

## CHAPTER 43

Diane M. Anderson, PhD, RD, CSP, FADA

# Medical Nutrition Therapy for Low-Birth-Weight Infants

### KEY TERMS

appropriate for gestational age (AGA)  
bronchopulmonary dysplasia (BPD)  
carnitine  
extrauterine growth restriction (EUGR)  
extremely low birthweight (ELBW)  
gastric gavage  
gestational age  
glucose load  
hemolytic anemia  
human milk fortifiers  
infancy  
infant mortality rate  
intrauterine growth restriction (IUGR)

kangaroo care  
large for gestational age (LGA)  
low birthweight (LBW)  
necrotizing enterocolitis (NEC)  
neonatal period  
neutral thermal environment  
osteopenia of prematurity  
perinatal period  
premature (preterm) infant  
respiratory distress syndrome (RDS)  
small for gestational age (SGA)  
surfactant  
term infant  
very low birthweight (VLBW)

The management of low birthweight (LBW) infants requiring intensive care is continually improving. With new technologies, enhanced understanding of pathophysiologic conditions of the **perinatal period** (from 28 weeks of gestation to 4 weeks after birth), current nutrition management principles, and regionalization of perinatal care, the mortality rate during **infancy**—that period from birth to 1 year of age—remains stable in the United States. In particular, the development and use of **surfactant**—a mixture of lipoproteins secreted by alveolar cells into the alveoli and respiratory air passages that contributes to the elastic properties of pulmonary tissue—has increased the survival of preterm infants, as has the use of antepartum corticosteroids. Most premature infants have the potential for long and productive lives (Hack, 2009).

Nutrition can be provided to LBW infants in many ways, each of which has certain benefits and limitations. The

infant's size, age, and clinical condition dictate the nutrition requirements and the way they can be met. Because of the complexities involved in the neonatal intensive care setting, a team that includes a registered dietitian trained in neonatal nutrition should make the decisions necessary to facilitate optimal nutrition. In regionalized perinatal care systems, the neonatal nutritionist may also consult with health care providers in community hospitals and public health settings.

### INFANT MORTALITY AND STATISTICS

In 2007 the **infant mortality rate** in the United States remains stable at 6.77 infant deaths per 1000 live births (Heron et al., 2010). More than 65% of these deaths occur in the neonatal period, with the leading causes being birth

defects, prematurity, and LBW. The preterm birth rate was 12.7% and the incidence of LBW was 8.2%. Both rates are decreased from the 2006 rate and mark a change from the previous 20-year increase in premature and LBW infants.

The United States' infant mortality rate remains higher than that for many industrialized countries (Heron et al., 2010). This discrepancy may be attributable to the inconsistent collection of mortality data among nations, which may falsely lower mortality rates in other countries. However the high incidence of premature infants born in the United States contributes to this high infant mortality rate (MacDorman and Mathews, 2009).

## PHYSIOLOGIC DEVELOPMENT

### Gestational Age and Size

At birth an infant who weighs less than 2500 g ( $5\frac{1}{2}$  lb) is classified as having a **low birthweight (LBW)**; an infant weighing less than 1500 g ( $3\frac{1}{3}$  lb) has a **very low birthweight (VLBW)**; and an infant weighing less than 1000 g ( $2\frac{1}{4}$  lb) has an **extremely low birthweight (ELBW)**. LBW may be attributable to a shortened period of gestation, prematurity, or a restricted intrauterine growth rate, which makes the infant small for gestational age (SGA).

The **term infant** is born between the 37th and 42nd weeks of gestation. A **premature (preterm) infant** is born before 37 weeks of gestation, whereas a postterm infant is born after 42 weeks of gestation.

Antenatally, an estimate of the infant's **gestational age** is based on the date of the mother's last menstrual period, clinical parameters of uterine fundal height, the presence of quickening (the first movements of the fetus that can be felt by the mother), fetal heart tones, or ultrasound evaluations. After birth, gestational age is determined by clinical assessment. Clinical parameters fall into two groups: (1) a series of neurologic signs, which depend primarily on postures and tone; and (2) a series of external characteristics that reflect the physical maturity of the infant. The New Ballard Score (Ballard et al., 1991) examination is a frequently used clinical assessment tool. An accurate assessment of gestational age is important for establishing nutritional goals for individual infants and differentiating the premature infant from the term SGA infant.

An infant who is **small for gestational age (SGA)** has a birth weight that is lower than the 10th percentile of the standard weight for that gestational age. An SGA infant whose intrauterine weight gain is poor, but whose linear and head growth are between the 10th and 90th percentiles on the intrauterine growth grid, has experienced **asymmetric intrauterine growth restriction (IUGR)**. An SGA infant whose length and occipital frontal circumference are also below the 10th percentile of the standards has **symmetric IUGR**. Symmetric IUGR, which usually reflects early and prolonged intrauterine deficit, is apparently more detrimental to later growth and development. Some infants can be SGA because they are genetically small, and these infants usually do well.

An infant whose size is **appropriate for gestational age (AGA)** has a birth weight between the 10th and 90th percentiles on the intrauterine growth chart. The obstetrician diagnoses IUGR when the fetal growth rate decreases. Serial ultrasound measurements document this reduction in fetal anthropometric measurements, which may be caused by maternal, placental, or fetal abnormalities. The future growth and development of infants who have had IUGR is diverse, depending on the specific cause of the IUGR and treatment. Some infants who suffered from IUGR are SGA, but many may plot as AGA infants at birth. Decreased fetal growth does not always result in an infant who is SGA.

An infant whose birth weight is above the 90th percentile on the intrauterine growth chart is **large for gestational age (LGA)**. Box 43-1 summarizes the weight classifications. Figure 43-1 shows the classification of neonates based on maturity and intrauterine growth.

### Characteristics of Immaturity

The premature or LBW infant has not had the chance to develop fully in utero and is physiologically different from the term infant (Figure 43-2). Because of this, LBW infants have various clinical problems in the early **neonatal period**, depending on their intrauterine environment, degree of prematurity, birth-related trauma, and function of immature or stressed organ systems. Certain problems occur with such frequency that they are considered typical of prematurity (Table 43-1). Premature infants are at high risk for poor nutrition status because of poor nutrient stores, physiologic immaturity, illness (which may interfere with nutritional management and needs), and the nutrient demands required for growth.

Most fetal nutrient stores are deposited during the last 3 months of gestation; therefore the premature infant begins life in a compromised nutritional state. Because metabolic (i.e., energy) stores are limited, nutrition support in the form of parenteral nutrition (PN), enteral nutrition (EN), or both should be initiated as soon as possible. In the preterm infant weighing 1000 g, fat constitutes only 1% of total body

### BOX 43-1

#### Classification of Birth Weight and Intrauterine Growth

Low birth weight < 2500 g

Very low birth weight < 1500 g

Extremely low birth weight < 1000 g

Small for gestational age = Birth weight < 10th percentile of standard for gestational age

Appropriate for gestational age = Birth weight between the 10th and 90th percentile of standard for gestational age

Large for gestational age = Birth weight > 90th percentile of standard for gestational age

**FIGURE 43-1** Classification of neonates based on maturity and intrauterine growth (small for gestational age [SGA], appropriate for gestational age [AGA], or large for gestational age [LGA]). (From Battaglia FC, Lubchenco LO: A practical classification of newborn infants by weight and gestational age, *J Pediatr* 71:159, 1967.)

**FIGURE 43-2** A.R., born at 27 weeks of gestation; birth weight of 870 g (1 lb, 14 oz).

weight; by contrast the term infant (3500 g) has a fat percentage of approximately 16%. For example, a 1000-g AGA premature infant has a glycogen and fat reserve equivalent to approximately 110 kcal/kg of body weight. With basal metabolic needs of approximately 50 kcal/kg/day, it is obvious that this infant will rapidly run out of fat and carbohydrate fuel unless adequate nutrition support is

**TABLE 43-1**

### Common Problems Among Premature Infants

System	Problem
Respiratory	Respiratory distress syndrome, chronic lung disease (bronchopulmonary dysplasia)
Cardiovascular	Patent ductus arteriosus
Renal	Fluid and electrolyte imbalance
Neurologic	Intraventricular hemorrhage, periventricular leukomalacia (cerebral necrosis)
Metabolic	Hypoglycemia, hyperglycemia, hypocalcemia, metabolic acidosis
Gastrointestinal	Hyperbilirubinemia, feeding intolerance, necrotizing enterocolitis
Hematologic	Anemia
Immunologic	Sepsis, pneumonia, meningitis
Other	Apnea, bradycardia, cyanosis, osteopenia

From Cloherty JP et al., editors: Manual of neonatal care, ed 6, Philadelphia, 2008, Wolters Kluwer/Lippincott Williams & Wilkins.

**TABLE 43-2**

### Expected Survival Time of Starved ( $H_2O$ Only) and Semistarved ( $D_{10}W$ ) Infants

Birth Weight (g)	Estimated Survival Time (Days)	
	$H_2O$	$D_{10}W$
1000	4	11
2000	12	30
3500	32	80

Data from Heird WC et al: Intravenous alimentation in pediatric patients, *J Pediatr* 80:351, 1972.

$D_{10}W$ , Dextrose 10% in water;  $H_2O$ , water.

established. The depletion time is even shorter for preterm infants weighing less than 1000 g at birth. Nutrient reserves are also depleted most quickly by tiny infants who have IUGR as a result of their decreased nutrient stores.

Theoretic estimates of survival time of starved and semistarved infants are shown in Table 43-2. These estimates assume depletion of all glycogen and fat and approximately one third of body protein tissue at a rate of 50 kcal/kg/day. The effects of fluids such as intravenously provided water (which has no exogenous calories) and 10% dextrose solution ( $D_{10}W$ ) are shown. Currently, PN fluids are started on the day of birth to provide energy and protein for the VLBW infant. Early protein intake promotes positive nitrogen balance, normal plasma amino acid levels, and glucose tolerance.

The small premature infant is particularly vulnerable to undernutrition. Malnutrition in premature infants may increase the risk of infection, prolong chronic illness, and adversely affect brain growth and function. In fact, [Lucas and colleagues \(1998\)](#) reported that the type of milk used for the neonatal diet may be directly linked to neurodevelopment at 18 months of age. Human milk or premature infant formula fed the first month of life resulted in improved development.

## NUTRITION REQUIREMENTS: PARENTERAL FEEDING

Many critically ill preterm infants have difficulty progressing to full enteral feedings in the first several days or even weeks of life. The infant's small stomach capacity, immature gastrointestinal tract, and illness make the progression to full enteral feedings difficult (see *Pathophysiology and Care Management Algorithm: Nutrition Support of Premature Infants*). PN becomes essential for nutrition support, either as a supplement to enteral feedings or as the total source of nutrition. [Chapter 14](#) offers a complete discussion of PN; only aspects related to feeding of the preterm infant are presented here.

### Fluid

Because fluid needs vary widely for preterm infants, fluid balance must be monitored. Inadequate intake can lead to dehydration, electrolyte imbalances, and hypotension; excessive intake can lead to edema, congestive heart failure, and possible opening of the ductus arteriosus. Additional neonatal clinical complications reported with high fluid intakes include necrotizing enterocolitis (NEC) and bronchopulmonary dysplasia (BPD) (see [Chapter 35](#)).

The premature infant has a greater percentage of body water (especially extracellular water) than the term infant (see [Chapter 7](#)). The amount of extracellular water should decrease in all infants during the first few days of life. This reduction is accompanied by a normal loss of 10% to 15% of body weight and improved renal function. Failure of this transition in fluid dynamics and lack of diuresis may complicate the course of preterm infants with respiratory disease.

Water requirements are estimated by the sum of the predicted losses from the lungs and skin, urine, and stool, and the water needed for growth. A major route of water loss in preterm infants is evaporation through the skin and respiratory tract. This insensible water loss is highest in the smallest and least mature infants because of their larger body surface area relative to body weight, increased permeability of the skin epidermis to water, and greater skin blood flow relative to metabolic rate. Insensible water loss is increased by radiant warmers and phototherapy lights and decreased by heat shields, thermal blankets, and humidified incubators. Insensible water loss can vary from 50 to 100 mL/kg/day on the first day of life and increase up to 120 to 200 mL/kg/day, depending on the infant's size, gestational age, day of life, and environment. The use of

humidified incubators can decrease insensible water losses and thereby reduce fluid requirements.

Excretion of urine, the other major route of water loss, varies from 24 to 72 mL/kg/day. This loss depends on the fluid volume and solute load presented to the kidneys. The infant's ability to concentrate urine increases with maturity. Stool water loss is generally 5 to 10 mL/kg/day, and 10 to 15 mL/kg/day is suggested as optimal for growth ([Dell and Davis, 2006](#)).

Because of the many variables affecting neonatal fluid losses, fluid needs must be determined on an individual basis. Usually fluid is administered at a rate of 80 to 105 mL/kg/day the first day of life to meet insensible losses and urine output. Fluid needs are then evaluated by assessing fluid intake and comparing it with the clinical parameters of urine output volume; urine specific gravity; and serum electrolyte, creatinine, and urea nitrogen levels. Assessments of weight, blood pressure, peripheral perfusion, skin turgor, and mucous membrane moisture are performed daily. Daily fluid administration generally increases by 10 to 20 mL/kg/day. By the end of the second week of life, preterm infants may receive fluids at a rate of 140 to 160 mL/kg/day. Fluid restriction may be necessary in preterm infants with patent ductus arteriosus, congestive heart failure, renal failure, or cerebral edema. However, more fluids are needed by preterm infants who are placed under phototherapy lights or a radiant warmer or when the environmental or body temperature is elevated.

### Energy

The energy needs of preterm infants fed parenterally are less than those of enterally fed infants because absorption loss does not occur when nutritional intake bypasses the intestinal tract. Enterally fed preterm infants usually require 105 to 130 kcal/kg/day to grow, whereas parenterally fed premature neonates can grow well if they receive 90 to 100 kcal/kg/day ([American Academy of Pediatrics \[AAP\], 2009b](#)). Minimum maintenance energy needs and adequate protein should be provided as soon as possible to prevent tissue catabolism. Providing VLBW infants with 1.5 to 2 g of protein and 30 to 50 kcal/kg/day promotes nitrogen balance during the first 3 days of life ([AAP, 2004](#); [AAP, 2009b](#)). Up to 3 g/kg/day of protein is tolerated ([Thureen et al., 2003](#)).

Energy and protein intake should be increased as the infant's condition stabilizes and growth becomes the goal ([Table 43-3](#)). Many VLBW infants are born AGA but at discharge from the hospital weigh less than the 10th percentile for their postmenstrual age. This new SGA status is called **extrauterine growth restriction (EUGR)**. EUGR may occur as a result of poor energy and protein intakes, and the decreased growth associated with illness ([Ehrenkranz, 2010](#)).

### Glucose

Glucose or dextrose is the principal energy source (3.4 kcal/g). However, glucose tolerance is limited in premature infants, especially in VLBW infants, because of inadequate insulin production, insulin resistance, and

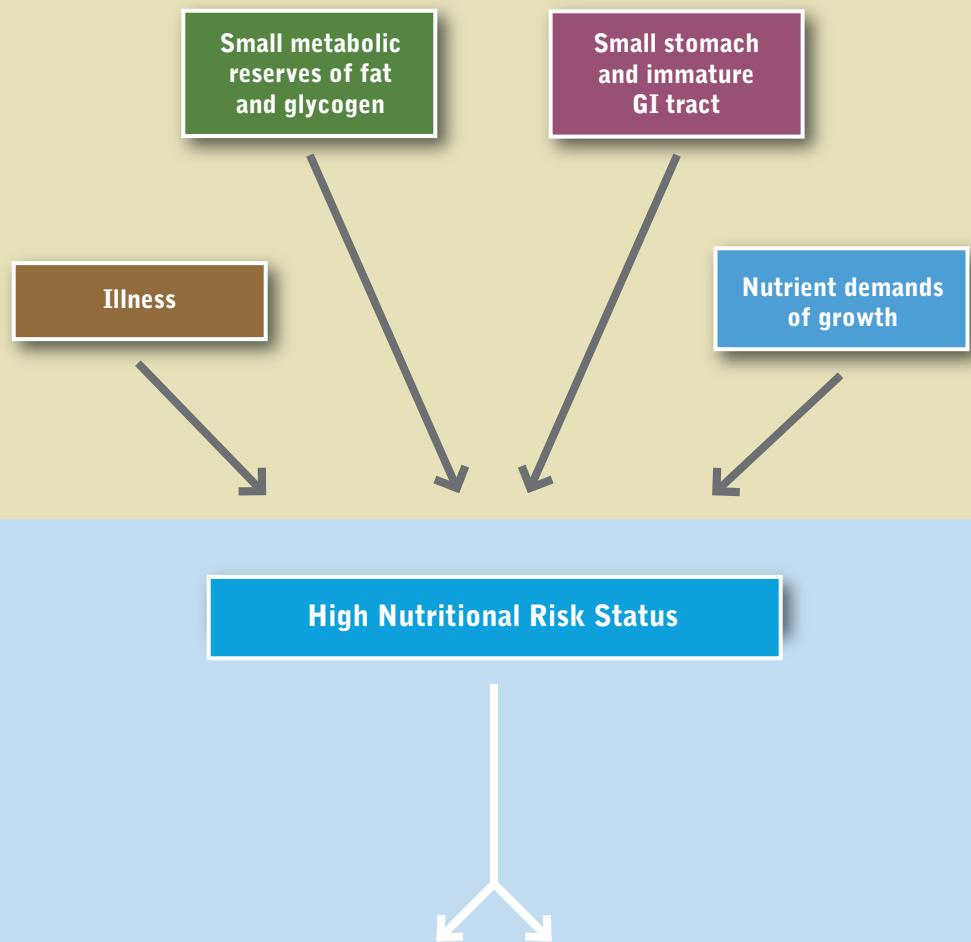

# PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

## Nutrition Support of Premature Infants

**TABLE 43-3**

### Comparison of Parenteral and Enteral Energy Needs of Premature Infants

	<b>Parenteral</b>	<b>Enteral</b>
<b>Maintenance</b>		
Gradually increase intake to meet energy needs by the end of the first week	30-50 cal/kg/day	50 kcal/kg/day
<b>Growth</b>		
Meet energy needs as soon as the infant's condition is stable	90-100 cal/kg/day	105-130 kcal/kg/day

continued hepatic glucose release while intravenous glucose is infusing. Hyperglycemia is less likely when glucose is administered with amino acids than when it is infused alone. Amino acids exert a stimulatory effect on insulin release. Prevention of hyperglycemia is important because it can lead to diuresis and dehydration.

To prevent hyperglycemia in VLBW infants, glucose should be administered in small amounts. The **glucose load** is a function of the concentration of the dextrose infusion and the rate at which it is administered (Table 43-4). The administration of exogenous insulin may be necessary for infants with persistent or very high glycemia, but changes in the infant's blood glucose level are common problems associated with its use. In addition, protein synthesis may be inhibited by insulin administration in premature infants (Denne, 2007).

In general, preterm infants should receive an initial glucose load of less than 6 mg/kg/min, with a gradual increase to 11 to 12 mg/kg/min. The glucose load can be advanced by 1 to 2 mg/kg/min/day. Hypoglycemia is not as common a problem as hyperglycemia, but it may occur if the glucose infusion is abruptly decreased or interrupted.

### Amino Acids

Protein guidelines range from 2.7 to 3.5 g/kg/day (AAP, 2009b). Some ELBW infants need as much as 3.5 to 4 g/kg/day (AAP, 2009b; Tsang et al., 2005). Protein in excess of these parenteral requirements should not be administered because additional protein offers no apparent advantage, and increases the risk of metabolic problems. In practice preterm infants are usually given 1.5 to 3 g/kg/day of protein for the first few days of life, and then protein is provided as tolerated. Many nurseries stock starter PN, which is water, glucose, protein, and perhaps calcium and is available 24 hours a day. Infants can then be provided with protein immediately on admission to the nursery.

In the United States several pediatric PN solutions are available. The use of pediatric PN solutions results in plasma amino acid profiles similar to those of fetal and cord blood or to those of healthy infants fed breast milk (Schanler and Anderson, 2008). These solutions promote adequate weight gain and nitrogen retention. Standard amino acid solutions were not designed to meet the particular needs of immature

infants and may provoke imbalances in plasma amino acid levels. For example, cysteine, tyrosine, and taurine levels in these solutions are low relative to the needs of the preterm infant; but the methionine and glycine levels are relatively high. Because premature infants do not effectively synthesize cysteine from methionine because of decreased concentrations of the hepatic enzyme cystathione, a cysteine supplement has been suggested. Cysteine is insoluble and unstable in solution; thus it is added as cysteine hydrochloride when the PN solution is prepared.

In addition to plasma amino acid imbalances, other metabolic problems associated with amino acid infusions in preterm infants include metabolic acidosis, hyperammonemia, and azotemia. These problems can be minimized by using the crystalline amino acid products that are available and by keeping the protein load within the recommended guidelines (Table 43-5).

### Lipids

Intravenous fat emulsions are used for two reasons: (1) to meet essential fatty acid (EFA) requirements and (2) to provide a concentrated source of energy. EFA needs can be met by providing 0.5 to 1 g/kg/day of lipids. Biochemical evidence of EFA deficiency has been noted during the first week of life in VLBW infants fed parenterally without fat. The clinical consequences of EFA deficiency may include coagulation abnormalities, abnormal pulmonary surfactant, and adverse effects on lung metabolism.

Lipids can be initiated at 1 to 2 g/kg/day and should be provided over 24 hours (AAP, 2009b). Lipids can be advanced by 1 to 2 g/kg/day until a rate of 3 g/kg/day is reached (Table 43-6). Plasma triglycerides should be monitored because elevated triglyceride levels may develop in infants with a decreased ability to hydrolyze triglycerides. These infants usually have lower gestational age, SGA status, infection, surgical stress, or liver disease. Monitoring of serum

**TABLE 43-4**

### Guidelines for Glucose Load in Premature Infants

Initial Load (mg/kg/min)*	Daily Increments (mg/kg/min)	Maximum Load (mg/kg/min)
4-6	1-2	11-12

\*Use the following formula to calculate glucose load: (% Glucose × mL/kg/day) × (1000 mg/g glucose) ÷ (1440 min/day). For example, (0.10 × 150 mL/kg/day) × (1000 mg/g glucose) ÷ (1440 min/day) = 10.4 mg/kg/min.

**TABLE 43-5**

### Guidelines for Administration of Parenteral Amino Acids for Premature Infants

Initial Rate (g/kg/day)*	Increments (g/kg/day)	Maximum Rate (g/kg/day)
1.5-3	Advance to meet needs	3.5-4†

Data from American Academy of Pediatrics, Committee on Nutrition: Nutritional needs of preterm infants. In Kleinman RE, editor: Pediatric nutrition handbook, ed 6, Elk Grove, IL, 2009, American Academy of Pediatrics.

\*Use the following formula to calculate protein load: % Protein × mL/kg/day = Protein g/kg/day.

For example: 2% amino acid parenteral solution provided at 150 mL/kg/day is × 0.02 × 150 mL/kg/day = 3 g/kg/day.

†From Tsang RC et al: Summary of reasonable nutrient intakes. In Tsang RC: Nutrition of the preterm infant, ed 2, Cincinnati, OH, 2005, Digital Educational Publishing, Inc. 4 g/kg/day is recommended for infants weighing less than 1000 g.

**TABLE 43-6****Guidelines for Administration of Parenteral Lipids for Premature Infants**

Initial Rate (g/kg/day)*	Increments (g/kg/day)	Maximum Rate (g/kg/day)
1-2	1	3

Data from American Academy of Pediatrics, Committee on Nutrition: Nutritional needs of preterm infants. In Kleinman RE, editor: *Pediatric nutrition handbook*, ed 6, Elk Grove, IL, 2009, American Academy of Pediatrics.

\*Use the following formula to calculate lipid load: % Lipid  $\times$  mL/kg/day = Lipid g/kg/day. For example, 0.20  $\times$  15 mL/kg = 3 g/kg/day.

**TABLE 43-7****Guidelines for Administration of Parenteral Electrolytes for Premature Infants**

Electrolyte	Amount (mEq/kg/day)
Sodium	2-4
Chloride	2-4
Potassium	1.5-2

**Electrolytes**

After the first few days of life, sodium, potassium, and chloride are added to parenteral solutions to compensate for the loss of extracellular fluid. To prevent hyperkalemia and cardiac arrhythmia, potassium should be withheld until renal flow is demonstrated. In general, the preterm infant has the same electrolyte requirements as the term infant, but actual requirements vary, depending on factors such as renal function, state of hydration, and the use of diuretics (Table 43-7). Very immature infants may have a limited ability to conserve sodium and thus may require increased amounts of sodium to maintain a normal serum sodium concentration. Serum electrolyte levels should be monitored periodically.

**Minerals**

Calcium and phosphorus are important components of the PN solution. Premature infants who receive PN with low calcium and phosphorus concentrations are at risk for developing osteopenia of prematurity. This poor bone mineralization is most likely to develop in VLBW infants who receive PN for prolonged periods. Calcium and phosphorus status should be monitored using serum calcium, phosphorus, and alkaline phosphatase activity levels (see Appendix 30 for normal range). Alkaline phosphatase activity levels in premature infants are greater than the levels seen with adults. It is common to see levels up to 600 IU/L, which may reflect rapid bone growth (Mitchell et al., 2009). When alkaline phosphatase activity levels of 800 IU/L or more persist, knee or wrist radiographs should be examined for rickets (Mitchell et al., 2009). Elevation in alkaline phosphatase activity may also be seen with liver disease.

Preterm infants have higher calcium and phosphorus needs than term infants. However, it is difficult to add enough calcium and phosphorus to parenteral solutions to meet these higher requirements without causing precipitation of the minerals. Calcium and phosphorus should be provided simultaneously in separate PN solutions. Alternate-day infusions are not recommended because abnormal serum mineral levels and decreased mineral retention develop.

Current recommendations for parenteral administration of additional calcium, phosphorus, and magnesium are presented in Table 43-8. The intakes are expressed at a volume intake of 120 to 150 mL/kg/day, with 2.5 g/100 mL of amino acids or protein. Lower fluid volumes or lower protein concentrations may cause the minerals to precipitate

triglyceride levels is indicated, and a rate of less than 3 g/kg/day of fat may be required to keep serum triglyceride levels under 200 mg/dL (AAP, 2009b). Once the infant is medically stable and additional energy is needed for growth, lipid loads can slowly be increased. Intralipids can be given to the infant with hyperbilirubinemia. At the present recommendation of 3 g/kg/day, given during 24 hours, the displacement of bilirubin from albumin-binding sites does not occur (AAP, 2009b).

The total lipid load is usually less than 30% to 40% of nonprotein calories, but it should not exceed 60% of nonprotein calories. (The lipid emulsions currently in use are described in Chapter 14). In preterm infants 20% solutions providing 2 kcal/mL are recommended because plasma triglyceride, cholesterol, and phospholipid levels are generally lower with these than with the 10% emulsions. The lower plasma fat levels may be attributable to a decreased phospholipid load per gram of fat in the 20% emulsion.

Intravenous fat emulsions are made from soybean oil and contain  $\omega$ -6 fatty acids, linoleic acid and arachidonic acid (ARA). These EFAs increase the production of inflammatory mediators and increase the infant's inflammatory state (Gura, 2010). There is a fish-oil base intravenous fat and it contains  $\omega$ -3 fatty acids: eicosapentaenoic acid and docosahexaenoic acid (DHA). These  $\omega$ -3 fatty acids are antiinflammatory and are helpful in the treatment of PN-associated liver disease (Gura, 2010). This fish-oil product is produced in Europe and requires approval for compassionate use by the Food and Drug Administration for patients in the United States. Investigations are ongoing to determine if this product can be used to prevent PN-associated liver disease, which presents with an elevated conjugated bilirubin.

Carnitine is frequently added to PN solutions provided to premature infants. Carnitine facilitates the mechanism by which fatty acids are transported across the mitochondrial membrane, allowing their oxidation to provide energy. Intravenous lipid does not contain carnitine and premature infants have limited ability to produce carnitine (Hay, 2008). Carnitine supplementation may be helpful for preterm infants who are receiving only PN for 2 to 4 weeks.

**TABLE 43-8****Guidelines for Administration of Parenteral Minerals for Premature Infants**

Minerals	Amount (mg/kg/day)*
Calcium	60-80
Phosphorus	39-67
Magnesium	4.3-7.2

From American Academy of Pediatrics, Committee on Nutrition: Nutritional needs of preterm infants. In Kleinman RE, editor: Pediatric nutrition handbook, ed 6, Elk Grove, IL, 2009, American Academy of Pediatrics.

\*These recommendations assume an average fluid intake of 120 to 150 mL/kg/day with 2.5 g of amino acids per 100 mL. The amino acid concentration prevents the precipitation of these minerals.

†Reduced or not provided for infants with renal dysfunction.

out of solution. The addition of cysteine hydrochloride increases the acidity of the fluid, which inhibits precipitation of calcium and phosphorus.

**Trace Elements**

Zinc should be given to all preterm infants receiving PN. If enteral feedings cannot be started by 2 weeks of age, additional trace elements should be added. However, the amounts of copper and manganese should be reduced for infants with obstructive jaundice; and the amounts of selenium, chromium, and molybdenum should be reduced in infants with renal dysfunction. Parenteral iron is not routinely provided because infants often receive blood transfusions soon after birth, and enteral feedings, which provide a source of iron, can often be initiated. If necessary, the dosage for parenteral iron is approximately 10% of the enteral dosage; guidelines range from 0.1 to 0.2 mg/kg/day (Rao and Georgieff, 2005). Recommended guidelines have not yet been established for parenteral administration of fluoride to preterm infants (Table 43-9).

**TABLE 43-10****Guidelines for Administration of Parenteral Vitamins for Premature Infants**

Preterm
Percentage of one 5-mL vial of MVI-Pediatric/ INFUVITE*
<i>MVI</i> , multivitamin for infusion.
Maximum volume intake is 5 mL/day, which is achieved at 2.5 kg body weight.

Data from American Academy of Pediatrics, Committee on Nutrition: Nutritional needs of preterm infants. In Kleinman RE, editor: Pediatric nutrition handbook, ed 6, Elk Grove, IL, 2009, American Academy of Pediatrics.

\*MVI-Pediatric/INFUVITE (5 mL) contains the following vitamins: 80 mg of ascorbic acid, 2300 USP units of vitamin A, 400 USP units of vitamin D, 1.2 mg of thiamin, 1.4 mg of riboflavin, 1 mg of vitamin B<sub>6</sub>, 17 mg of niacin, 5 mg of pantothenic acid, 7 USP units of vitamin E, 20 mcg of biotin, 140 mcg of folic acid, 1 mcg of vitamin B<sub>12</sub>, and 200 mcg of vitamin K.

**Vitamins**

Shortly after birth all newborn infants receive an intramuscular (IM) injection of 0.5 to 1 mg of vitamin K to prevent hemorrhagic disease of the newborn from vitamin K deficiency. Stores of vitamin K are low in newborn infants, and there is little intestinal bacterial production of vitamin K until bacterial colonization takes place. Because initial dietary intake of vitamin K is limited, neonates are at nutritional risk if they do not receive this IM supplement.

Only intravenous multivitamin preparations currently approved and designed for use in infants should be given to provide the appropriate vitamin intake and prevent toxicity from additives used in adult multivitamin injections. The American Academy of Pediatrics (AAP, 2009b) recommends 40% of the multivitamin for infusion (MVI)-pediatric 5-mL vial per kilogram of weight. The maximum dose of 5 mL is given to an infant with a weight of 2.5 kg (Table 43-10).

**Respiratory distress syndrome (RDS)** is a disease that occurs in premature infants shortly after birth because these infants are deficient in the lung substance surfactant. Surfactant is responsible for keeping the lung elastic while breathing; thus surfactant supplements are given to the infant to prevent RDS or to lessen the illness. Lipids and proteins are components of surfactant, and phospholipids are the major lipid. Choline is required for phospholipid synthesis, but choline supplementation does not increase the production of phospholipids (van Aerde and Narvey, 2006). Choline is a conditionally essential nutrient because the infant can synthesize choline (see Chapter 16 for a discussion of requirement for choline in pregnancy). Choline is added to premature infant formulas at the level contained in human milk. The upper level is extrapolated from the adult safe level of intake (Klein, 2002).

**Bronchopulmonary dysplasia (BPD)** is a chronic lung disease that commonly develops in the premature infant as

a result of RDS and the mechanical ventilation and oxygen used to treat it. Because of the role of vitamin A in facilitating tissue repair, and because of reports of preterm infants having low vitamin A stores, large supplemental doses of vitamin A have been suggested for the prevention of BPD. One report suggests that providing ELBW premature infants with IM injections of vitamin A at 5000 units/day three times per week during the first month of life decreases the incidence of BPD (Tyson et al., 1999). Physicians may or may not use this supplementation. The decision will be based on the incidence of BPD in their nursery, the lack of proven additional benefits and the acceptability of using IM injections (Darlow and Graham, 2008). See Chapter 35 for discussion of BPD.

## TRANSITION FROM PARENTERAL TO ENTERAL FEEDING

It is beneficial to begin enteral feedings for preterm infants as early as possible because the feedings stimulate gastrointestinal enzymatic development and activity, promote bile flow, increase villous growth in the small intestine, and promote mature gastrointestinal motility. These initial enteral feedings can also decrease the incidence of cholestatic jaundice and the duration of physiologic jaundice and can improve subsequent feeding tolerance in preterm infants. At times small, initial feedings are used only to prime the gut and are not intended to optimize enteral nutrient intake until the infant demonstrates feeding tolerance or is clinically stable.

When making the transition from parenteral to enteral feeding, it is important to maintain parenteral feeding until enteral feeding is well established to maintain adequate net intake of fluid and nutrients. In VLBW infants it may take 7 to 14 days to provide a full enteral feeding, and it may take longer for infants with feeding intolerances or illness. The smallest, sickest infants usually receive increments of only 10 mL/kg/day. Larger, more stable preterm infants may tolerate increments of 20 to 30 mL/kg/day (see Chapter 14 for a more detailed discussion of transitional feeding).

## NUTRITION REQUIREMENTS: ENTERAL FEEDING

Enteral alimentation is preferred for preterm infants because it is more physiologic than parenteral alimentation and is nutritionally superior. Initiating a tiny amount of an appropriate breast milk feeding whenever possible is beneficial (Sisk et al., 2007). However, determining when and how to provide enteral feedings is often difficult and involves consideration of the degree of prematurity, history of perinatal insults, current medical condition, function of the gastrointestinal tract, respiratory status, and several other individual concerns (Table 43-11).

Preterm infants should be fed enough to promote growth similar to that of a fetus at the same gestational age, but not so much that nutrient toxicity develops. Although the

**TABLE 43-11**

### Factors to Consider Before Initiating or Increasing the Volume of Enteral Feedings

Category	Factors
Perinatal	Cardiorespiratory depression
Respiratory	Stability of ventilation, blood gases, apnea, bradycardia, cyanosis
Medical	Vital signs (heart rate, respiratory rate, blood pressure, temperature)
Gastrointestinal	Anomalies (gastroschisis, omphalocele), patency, gastrointestinal tract function (bowel sounds present, passage of stool), risk of necrotizing enterocolitis
Infection	Sepsis or suspect sepsis

Data from Adamkin DH: Nutritional strategies for the very low birthweight infant, Cambridge, 2009, Cambridge University Press; Hay WW: Strategies for feeding the preterm infant, *Neonatol* 94:245, 2008.

exact nutrient requirements are unknown for preterm infants, several useful guidelines exist. In general the requirements of premature infants are higher than those of term infants because the preterm infant has smaller nutrient stores, decreased digestion and absorption capabilities, and a rapid growth rate. Stress, illness, and certain therapies for illness may further influence nutrient requirements. It is also important to remember that, in general, enteral nutrient requirements are different from parenteral requirements.

### Energy

The energy requirements of premature infants vary with individual biologic and environmental factors. It is estimated that an intake of 50 kcal/kg/day is required to meet maintenance energy needs, compared with 105 to 130 kcal/kg/day for growth (Table 43-12). However, energy needs may be increased by stress, illness, and rapid growth. Likewise, energy needs may be decreased if the infant is placed in a **neutral thermal environment** (the environmental temperature at which an infant expends the least amount of energy to maintain body temperature). It is important to consider the infant's rate of growth in relation to average energy intakes. Some premature infants may need greater than 130 kg/day to sustain an appropriate rate of growth. ELBW infants or those with BPD often require such increased amounts. To provide such a large number of calories to infants with a limited ability to tolerate large fluid volumes, it may be necessary to concentrate the feedings to a level of more than 24 kcal/oz (Box 43-2).

### Protein

The amount and quality of protein must be considered when establishing protein requirements for the preterm infant. Amino acids should be provided at a level that meets demands without inducing amino acid or protein toxicity.

**TABLE 43-12****Estimation of Energy Requirements of the Low-Birth-Weight Infant**

Activity	Average Estimation (kcal/kg/day)
Energy expended	40-60
Resting metabolic rate	40-50*
Activity	0-5*
Thermoregulation	0-5*
Synthesis	15†
Energy stored	20-30†
Energy excreted	15
Energy intake	90-120

\*Energy for maintenance.  
†Energy cost of growth.

**BOX 43-2****Recipes for Preparing 90 mL (3 oz) of Concentrated Premature Infant Formula**

Kcal/oz	Ratio	Volume (mL)	Volume RTF*
RTF*	24/30 kcal oz	RTF*	(mL)
Formula	RTF Formula	Premature 24	Premature 30
24	1/0	90	0
26	2/1	60	30
27	1/1	45	45
28	1/2	30	60
30	0/1	0	90

RTF, Ready-to-Feed formula.

\*RTF (at 24 and 30 kcal/oz).

Example: Recipe for Making a 26 kcal/oz formula:

Goal = 90 mL (3 oz) of formula

2 parts of 24 kcal/oz formula + 1 part of 30 kcal/oz formula = 3 parts of formula

90 mL ÷ 3 parts = 30 mL per part

30 mL × 2 parts = 60 mL of RTF Premature 24 kcal/oz formula + 30 mL × 1 part = 30 mL of Premature 30 kcal/oz = 90 mL (3 parts) of 26 kcal/oz formula

this method for determining protein needs, the advisable protein intake is 3.5 to 4 g/kg/day. This amount of protein is well tolerated.

The quality or type of protein is an important consideration because premature infants have different amino acid needs than term infants because of immature hepatic enzyme pathways. The amino acid composition of whey protein, which differs from that of casein, is more appropriate for premature infants. The essential amino acid cysteine is more highly concentrated in whey protein, and premature infants do not synthesize cysteine well. In addition, the amino acids phenylalanine and tyrosine are lower, and the preterm infant has difficulty oxidizing them. Furthermore, metabolic acidosis decreases with consumption of whey-predominant formulas. Because of the advantages of whey protein for premature infants, breast milk or formulas containing predominately whey proteins should be chosen whenever possible.

Taurine is a sulfonic amino acid that may be important for preterm infants. Human milk is a rich source of taurine, and taurine is added to most infant formulas. Term and preterm infants develop low plasma and urine concentrations of taurine without a dietary supply. The premature infant may have difficulty with synthesizing taurine from cysteine. Although no overt disease has been reported in infants fed low taurine formulas, low taurine may affect the development of vision and hearing (Klein, 2002).

Energy must be provided at sufficient levels to allow protein to be used for growth and not merely for energy expenditure. A range of 10.2% to 12.4% of calories from protein has been suggested. Inadequate protein intake is growth limiting, whereas excessive intake causes elevated plasma amino acid levels, azotemia, and acidosis.

**Lipids**

The growing preterm infant needs an adequate intake of well-absorbed dietary fat to help meet the high energy needs of growth, provide EFAs, and facilitate absorption of other important nutrients such as the fat soluble vitamins and calcium. However, neonates in general, and premature and SGA infants in particular, digest and absorb lipids inefficiently.

Fat should constitute 40% to 50% of total calories. Furthermore, a diet that is high in fat and low in protein may yield more fat deposition than is desirable for the growing preterm infant. To meet EFA needs, linoleic acid should compose 3% of the total calories, and α-linolenic acid should be added in small amounts (AAP, 2009b). Additional longer-chain fatty acids—ARA and DHA—are present in human milk and are added to infant formulas for term and premature infants to meet federal guidelines.

The premature infant has a greater need than the term infant for ARA and DHA supplementation. These fatty acids accumulate in fatty tissue and the brain during the last 3 months of gestation; thus the premature infant has decreased stores. Premature infants fed formulas supplemented with ARA and DHA from birth to 92 weeks' postmenstrual age (12 months after term) demonstrate greater

A reference fetus model has been used to determine the amount of protein that needs to be ingested to match the quantity of protein deposited into newly formed fetal tissue (Ziegler, 2007). To achieve these fetal accretion rates, additional protein must be supplied to compensate for intestinal losses and obligatory losses in the urine and skin. Based on

gain in weight and length and higher psychomotor development scores than premature infants not receiving the fatty acid supplementation (Clandinin et al., 2005).

Preterm infants have low levels of pancreatic lipase and bile salts, and this decreases their ability to digest and absorb fat. Lipases are needed for triglyceride breakdown, and bile salts solubilize fat for ease of digestion and absorption. Because medium-chain triglycerides (MCTs) do not require pancreatic lipase and bile acids for digestion and absorption, they have been added to the fat mixture in premature infant formulas. Human milk and vegetable oils contain the EFA linoleic acid, but MCT oil does not. Premature infant formulas must contain vegetable oil and MCT oil to provide the essential long-chain fatty acids.

The composition of dietary fat also plays a role in the digestion and absorption of lipid. In general, infants absorb vegetable oils more efficiently than saturated animal fats, although one exception is the saturated fat in human milk. Infants digest and absorb human milk fat better than the saturated fat in cow's milk or the vegetable oil in standard infant formulas. Human milk contains two lipases that facilitate fat digestion and has a special fatty acid composition that aids absorption.

## Carbohydrates

Carbohydrates are an important source of energy, and the enzymes for endogenous production of glucose from carbohydrate and protein are present in preterm infants. Approximately 40% of the total calories in human milk and standard infant formulas are derived from carbohydrates. Too little carbohydrate may lead to hypoglycemia, whereas too much may provoke osmotic diuresis or loose stools. The recommended range for carbohydrate intake is 40% to 50% of total calories.

Lactose, a disaccharide composed of glucose and galactose, is the predominant carbohydrate in almost all mammalian milks and may be important to the neonate for glucose homeostasis, perhaps because galactose can be used for either glucose production or glycogen storage. Generally galactose is used for glycogen formation first, and then it becomes available for glucose production as blood glucose levels decrease. Because infants born before 28 to 34 weeks of gestation have low lactase activity, the premature infant's ability to digest lactose may be marginal. In practice, malabsorption is not a clinical problem because lactose is hydrolyzed in the intestine or fermented in the colon and absorbed. Sucrose is another disaccharide that is commonly found in commercial infant formula products. Because sucrase activity early in the third trimester is at 70% of newborn levels, sucrose is well tolerated by most premature infants. Sucrase and lactase are sensitive to changes in the intestinal milieu. Infants who have diarrhea, are undergoing antibiotic therapy, or are undernourished, may develop temporary intolerances to lactose and sucrose.

Glucose polymers are common carbohydrates in the preterm infant's diet. These polymers, consisting mainly of chains of five to nine glucose units linked together, are used to achieve the isoosmolality of certain specialized formulas.

**TABLE 43-13**

### Recommendations for Enteral Administration of Vitamins for the Premature Infant

Vitamin	Amount (kg/day)
Vitamin A	700-1500 IU
Vitamin D	150-400 IU*
Vitamin E	6-12 IU
Vitamin K	8-10 mcg
Ascorbic acid	18-24 mg
Thiamin	180-240 mcg
Riboflavin	250-360 mcg
Pyridoxine	150-210 mcg
Niacin	3.6-4.8 mg
Pantothenate	1.2-1.7 mg
Biotin	3.6-6 mcg
Folate	25-50 mcg
Vitamin B <sub>12</sub>	0.3 mcg

Data from American Academy of Pediatrics, Committee on Nutrition: Nutritional needs of preterm infants. In Kleinman RE, editor: Pediatric nutrition handbook, ed 6, Elk Grove, IL, 2009, American Academy of Pediatrics.

\*Maximum of 400 IU/day.

Glucosidase enzymes for digesting glucose polymers are active in small preterm infants.

## Minerals and Vitamins

Premature infants require greater amounts of vitamins and minerals than term infants because they have poor body stores, are physiologically immature, are frequently ill, and will grow rapidly. Formulas and **human milk fortifiers** that are developed especially for preterm infants contain higher vitamin and mineral concentrations to meet the needs of the infant, obviating the need for additional supplementation in most cases (Table 43-13). One major exception is infants receiving human milk with a fortifier that does not contain iron. An iron supplement of 2 mg/kg/day should be sufficient to meet their needs (AAP, 2009b). The other exception is the use of donor human milk fortifier, which requires the addition of a multiple vitamin and an iron supplement.

## Calcium and Phosphorus

Calcium and phosphorus are just two of many nutrients that growing premature infants require for optimal bone mineralization. Intake guidelines have been established at levels that promote the bone mineralization rate that occur in the fetus. An intake of 100-220 mg/kg/day of calcium and 60-140 mg/kg/day of phosphorus is recommended. Two thirds of the calcium and phosphorus body content of the term neonate is accumulated through active transport mechanisms during the last trimester of pregnancy. Infants who are born prematurely are deprived of this important intrauterine mineral deposition. With poor mineral stores and low dietary intake, preterm infants can

develop **osteopenia of prematurity**, a disease characterized by demineralization of growing bones and documented by radiologic evidence of “washed-out” or thin bones. Very immature babies are particularly susceptible to osteopenia and may develop bone fractures or florid rickets with a prolonged dietary deficiency. Osteopenia of prematurity is most likely to develop in preterm infants who are (1) fed infant formula that is not specifically formulated for preterm infants, (2) fed human milk that is not supplemented with calcium and phosphorus, or (3) receiving long-term PN without enteral feedings.

## Vitamin D

Human milk with human milk fortifier or infant formula for preterm infants provides adequate vitamin D when infants consume the entire calorie intake suggested. The current recommendations for intake range from 150 to 400 IU/day for preterm infants.

## Vitamin E

Preterm infants require more vitamin E than term infants because of their limited tissue stores, decreased absorption of fat-soluble vitamins, and rapid growth. Vitamin E protects biologic membranes against oxidative lipid breakdown. Because iron is a biologic oxidant, a diet high in either iron or polyunsaturated fatty acids (PUFAs) increases the risk of vitamin E deficiency. The PUFAs are incorporated into the red blood cell membranes and are more susceptible to oxidative damage than when saturated fatty acids compose the membranes.

A premature infant with vitamin E deficiency may experience **hemolytic anemia** (oxidative destruction of red blood cells). However, this anemia is now uncommon today because of improvements in human milk fortifiers and infant formula composition. The human milk fortifiers and premature infant formulas now contain appropriate vitamin E/PUFA ratios for preventing hemolytic anemia.

Because the dietary requirement for vitamin E depends on the PUFA content of the diet, the recommended intake of vitamin E is commonly expressed as a ratio of vitamin E to PUFA. The recommendation for vitamin E is 0.7 IU (0.5 mg of d- $\alpha$ -tocopherol) per 100 kcal, and at least 1 IU of vitamin E per gram of linoleic acid.

Pharmacologic dosing of vitamin E (50 to 100 mg/kg/day) has not proven to be helpful in preventing BPD or retinopathy of prematurity by reducing the toxic effects of oxygen. Furthermore, high doses of vitamin E have been associated with intraventricular hemorrhage, sepsis, NEC, liver and renal failure, and death.

## Iron

Preterm infants are at risk for iron deficiency anemia because of the reduced iron stores associated with early birth. At birth most of the available iron is in the circulating hemoglobin. Thus frequent blood sampling further depletes the amount of iron available for erythropoiesis. Transfusions of red blood cells are often needed to treat the early physiologic anemia of prematurity. Recombinant erythropoietin

(EPO) therapy has been used to prevent anemia. Iron supplementation is indicated to facilitate red blood cell production, and a dosage of 6 mg/kg/day of enteral iron has been used (AAP, 2009b). This therapy has not consistently prevented anemia and the need for blood transfusions (AAP, 2009b).

In general the recommendation for iron intake is 2 to 4 mg/kg/day (AAP, 2009b). Infants fed human milk should be given ferrous sulfate drops beginning at 1 month of age (Baker and Greer, 2010). Formulas fortified with iron usually contain sufficient iron for preterm infants (AAP, 2009b).

## Folic Acid

Premature infants seem to have higher folic acid needs than infants born at term. Although serum folate levels are high at birth, they decrease dramatically, probably as a result of high folic acid use by the premature infant for deoxyribonucleic acid and tissue synthesis needed for rapid growth.

A mild form of folic acid deficiency causing low serum folate concentrations and hypersegmentation of neutrophils is not unusual in premature infants. Megaloblastic anemia is much less common. A daily folic acid intake of 25 to 50 mcg/kg effectively maintains normal serum folate concentrations. Fortified human milk and formulas for premature infants meet these guidelines when full enteral feedings are established.

## Sodium

Preterm infants, especially those with VLBW, are susceptible to hyponatremia during the neonatal period. These infants may have excessive urinary sodium losses because of renal immaturity and an inability to conserve adequate sodium. Furthermore, their sodium needs are high because of their rapid growth rate.

Daily sodium intakes of 4 to 8 mEq/kg or more may be required by some infants to prevent hyponatremia. Routine sodium supplementation of fortified human milk and infant formulas is not necessary. However, it is important to consider the possibility of hyponatremia and monitor infants by assessing serum sodium until the blood level is normal. Milk can be supplemented with sodium if repletion is necessary.

## FEEDING METHODS

Decisions about breast-feeding, bottle-feeding, or tube-feeding depend on the gestational age and the clinical condition of the preterm infant. The goal is to feed the infant via the most physiologic method possible and supply nutrients for growth without creating clinical complications.

### Gastric Gavage

Gastric gavage by the oral route is often chosen for infants who are unable to suck because of immaturity or problems with the central nervous system. Infants less than 32 to 34 weeks of gestational age, regardless of birth weight have poorly coordinated sucking, swallowing, and breathing

abilities because of their developmental immaturity. Consequently they have difficulty with nipple-feeding.

With the oral **gastric gavage** method, a soft feeding tube is inserted through the infant's mouth and into the stomach. The major risks of this technique include aspiration and gastric distention. Because of weak or absent cough reflexes and poorly developed respiratory muscles, the tiny infant may not be able to dislodge milk from the upper airway, which can cause reflex bradycardia or airway obstruction. However, electronic monitoring of vital functions and proper positioning of the infant during feeding minimize the risk of aspiration from regurgitation of stomach contents. Tiny, immature infants whose small gastric capacity and slow intestinal motility can impede the tolerance of large-volume bolus feeds may need bolus feedings provided with a pump for a 30 to 60 minute infusion to aid in feeding tolerance.

Occasionally elimination of the distention and vagal bradycardia requires the use of an indwelling tube for continuous gastric gavage feedings rather than intermittent administration of boluses. Continuous feedings may lead to loss of milk fat, calcium, and phosphorus, which deposit in the feeding tubing so that the infant does not receive the total amount of nutrition provided. Bolus feedings provided with the use of the pump infusion can decrease nutrient loss and promote better weight gain. (Hay, 2008; Rogers et al., 2010).

Nasal gastric gavage is sometimes better tolerated than oral tube-feeding. However, because neonates must breathe through the nose, this technique may compromise the nasal airway in preterm infants and cause an associated deterioration in respiratory function. This method is helpful for infants who are learning to nipple-feed. An infant with a nasal gastric tube can still form a tight seal on the bottle nipple, but it can be difficult if an oral feeding tube is in place during feedings (see Chapter 14).

### Transpyloric Feeding

Transpyloric tube-feeding is indicated for infants who are at risk for aspirating milk into the lungs or who have slow gastric emptying. The goal of this method is to circumvent the often slow gastric emptying of the immature infant by passing the feeding tube through the stomach and pylorus and placing its tip within the duodenum or jejunum. Infants with severe gastrointestinal reflux do well with this method, which prevents aspiration of feedings into the lungs. This method is also used for infants whose respiratory function is compromised and who are at risk for milk aspiration. The possible disadvantages of transpyloric feedings include decreased fat absorption, diarrhea, dumping syndrome, alterations of the intestinal microflora, intestinal perforation, and bilious fluid in the stomach. In addition, the placement of transpyloric tubes also requires considerable expertise and radiographic confirmation of the catheter tip location. Although associated with many possible complications, transpyloric feedings are used when gastric feeding is not successful.

### Nipple-Feeding

Nipple-feeding may be attempted with infants whose gestational age is greater than 32 weeks and whose ability to feed from a nipple is indicated by evidence of an established sucking reflex and sucking motion. Before this time they are unable to coordinate sucking, swallowing, and breathing. Because sucking requires effort by the infant, any stress from other causes such as hypothermia or hypoxemia diminishes the sucking ability. Therefore nipple-feeding should be initiated only when the infant is under minimum stress and is sufficiently mature and strong to sustain the sucking effort. Initial oral feedings may be limited to one to three times per day to prevent undue fatigue or too much energy expenditure, either of which can slow the infant's rate of weight gain. Before oral feedings begin, a standardized oral stimulation program can help infants successfully nipple-feed more quickly (Fucile et al., 2005).

### Breast-Feeding

When the mother of a premature infant chooses to breastfeed, nursing at the breast should begin as soon as the infant is ready. Before this time the mother must express her milk so that it can be tube-fed to her infant. These mothers need emotional and educational support for successful lactation. Studies report that premature breast-fed infants have better sucking, swallowing, and breathing coordination and fewer breathing disruptions than bottle-fed infants (Hurst, 2007).

**Kangaroo care**—allowing the mother to maintain skin-to-skin contact while holding her infant—facilitates her lactation. In addition, this type of contact promotes continuation of breast-feeding and enhances the mother's confidence in caring for her high-risk infant. The latter benefit may also apply to fathers who engage in kangaroo care with their infants (Stevens et al., 2010).

Feeding infants with cups instead of bottles to supplement breast-feeding has been suggested for preterm infants based on the rationale that it may prevent infant "nipple confusion" (i.e., confusion between nursing at the breast and from a bottle). Complications such as milk aspiration and low volume intakes need to be monitored. Cup feeding has been associated with successful breast-feeding at discharge, but increased length of stay in the hospital for the premature infant (Collins et al., 2008).

### Tolerance of Feedings

All preterm babies receiving EN should be monitored for signs of feeding intolerance. Vomiting of feedings usually signals the infant's inability to retain the provided amount of milk. When not associated with other signs of a systemic illness, vomiting may indicate that feeding volumes were increased too quickly or are excessive for the infant's size and maturity. Simply reducing the feeding volume may resolve the problem. If not, or if the infant has signs of a systemic illness, feedings may need to be interrupted until the infant's condition has stabilized.

Abdominal distention may be caused by excessive feeding, organic obstruction, excessive swallowing of air,

resuscitation, sepsis (i.e., systemic infection), or NEC. Observing infants for abdominal distention should be a routine practice for nurses. Abdominal distention often indicates the need to interrupt feeding until its cause is determined and resolved.

Gastric residuals, measured by aspiration of the stomach contents, may be determined routinely before each bolus gavage feeding and intermittently in all continuous drip feedings. Whether a residual amount is significant depends partly on its volume in relation to the total volume of the feeding. For example, a residual volume of more than 50% of a bolus feeding or equal to the continuous infusion rate might be a sign of feeding intolerance. However, when interpreting the significance of a gastric residual measurement, it is important to consider other concurrent signs of feeding intolerance and the previous pattern of residual volumes established for a particular infant. Residuals are frequently present before feedings are initiated and as small volume feedings are started. As long as no signs of illness are present, feedings should not be held.

Bile-stained emesis or residuals frequently may be due to overdistention of the stomach with reflux of bile from the intestine or to a feeding tube that has slipped into the intestine, or may indicate that the infant has an intestinal blockage and needs additional evaluation (Schanler and Anderson, 2008). Bloody or bilious gastric residuals are more alarming than those that seem to be undigested milk.

The frequency and consistency of bowel movements should be constantly monitored when feeding preterm infants. Simple inspections can detect the presence of gross blood. All feeding methods for preterm infants have associated complications. Unless close attention is paid to symptoms that indicate poor feeding tolerance, serious complications may ensue. Certain diseases can be recognized by recognizing signs of feeding intolerance. For example, **necrotizing enterocolitis (NEC)** is a serious and potentially fatal disease associated with specific symptoms such as abdominal distention and tenderness, abnormal gastric residuals, and grossly bloody stools.

## SELECTION OF ENTERAL FEEDING

During the initial feeding period premature infants often require additional time to adjust to EN and may experience concurrent stress, weight loss, and diuresis. The primary goal of enteral feeding during this initial period is to establish tolerance to the milk. Infants seem to need a period of adjustment to be able to assimilate a large volume and concentration of nutrients. Thus parenteral fluids may be necessary until infants can tolerate adequate amounts of feedings by mouth.

After the initial period of adjustment, the goal of enteral feeding changes from establishing milk tolerance to providing complete nutrition support for growth and rapid organ development. All essential nutrients should be provided in

quantities that support sustained growth. The following feeding choices are appropriate: (1) human milk supplemented with human milk fortifier and iron and vitamins as indicated by fortifier used, (2) iron-fortified premature infant formula for infants who weigh less than 2 kg, or (3) iron-fortified standard infant formula for infants who weigh more than 2 kg.

Premature infants who are discharged from the hospital can be given a transitional formula. Additional vitamin D may be indicated to provide 400 IU per day (Wagner and Greer, 2008). Iron supplements may be needed for some infants with the use of this enriched formula (Baker and Greer, 2010). Breast-fed infants may be provided with two to three bottles of transitional formula daily to meet needs. The breast-fed premature infant should also receive 2 mg/kg/day of iron and a multiple vitamin for the first year of life (AAP, 2009b). Premature infants discharged home on standard formula should receive a multivitamin until the infant reaches 3 kg in weight (AAP, 2009b).

## Human Milk

Human milk is the ideal food for healthy term infants and premature infants. Although human milk requires nutrient supplementation to meet the needs of premature infants, its benefits for the infant are numerous. During the first month of lactation, the composition of milk from mothers of premature infants differs from that of mothers who have given birth to term infants; the protein and sodium concentrations of breast milk are higher in mothers with preterm infants (Klein, 2002). When premature infants are fed their own mother's milk, they grow more rapidly than infants fed banked, mature breast milk (Schanler et al., 2005).

In addition to its nutrient concentration, human milk offers nutritional benefits because of its unique mix of amino acids and long-chain fatty acids. The zinc and iron in human milk are more readily absorbed, and fat is more easily digested because of the presence of lipases. Moreover, human milk contains factors that are not present in formulas. These components include (1) macrophages and T and B lymphocytes; (2) antimicrobial factors - secretory immunoglobulin A, lactoferrin, and others; (3) hormones; (4) enzymes; and (5) growth factors. It has been reported that human milk as compared with premature infant formula fed to preterm infants reduces the incidence of NEC and sepsis, improves neurodevelopment, facilitates a more rapid advancement of enteral feedings, and leads to an earlier discharge (Sisk et al., 2007; Sisk et al., 2008). The use of mother's own milk for her infant supplemented with liquid donor human milk fortifier and donor human milk is linked to decreased incidence of NEC (Sullivan et al., 2010).

However, one well-documented problem is associated with feeding human milk to preterm infants. Whether it is preterm, term, or mature, human milk does not meet the calcium and phosphorus needs for normal bone mineralization in premature infants. Therefore calcium and phosphorus supplements are recommended for rapidly growing

preterm infants who are fed predominantly human milk. Currently three human milk fortifiers are available: powder bovine milk base, liquid bovine milk base, and liquid donor human milk base. The bovine products contain calcium and phosphorus, as well as protein, carbohydrates, fat, vitamins, and minerals, and are designed to be added to expressed breast milk fed to premature infants (Table 43-14). Vitamin supplements are not needed. One bovine fortifier is iron fortified and the other requires the addition of iron. The human-milk base product is made from donor human milk that has been pasteurized, concentrated, and supplemented with calcium, phosphorous, zinc, and electrolytes. A multi-vitamin and an iron supplement is needed with the use of the human-milk base fortifier.

Providing human milk to a premature infant can be a very positive experience for the mother, one that promotes involvement and interaction. Because many preterm infants are neither strong enough nor mature enough to nurse at their mother's breast in the early neonatal period, their mothers usually express their milk for several days (and occasionally for several weeks) before nursing can be established. The proper technique of expression, storage, and transport of milk should be reviewed with the mother (see Chapter 16). Many summaries of the special considerations for nursing a preterm infant have been published (AAP and the American College of Obstetricians and Gynecologists, 2006; Hurst, 2007).

### Premature Infant Formulas

Formula preparations have been developed to meet the unique nutritional and physiologic needs of growing preterm infants. The quantity and quality of nutrients in these products promote growth at intrauterine rates. These formulas, which have caloric densities of 20, 24, and 30 kcal/oz, are available only in a ready-to-feed form. These premature formulas differ in many respects from standard cow's milk-based formulas (see Table 43-14). The types of carbohydrate, protein, and fat differ to facilitate digestion and absorption of nutrients. These formulas also have higher concentrations of protein, minerals, and vitamins.

### Transitional Infant Formulas

Formulas containing 22 kcal/oz have been designed as transition formulas for the premature infant. Their nutrient content is less than that of the nutrient-dense premature infant formulas and more than that of the standard infant formula (see Table 43-14). These formulas can be introduced when the infant reaches a weight of 2000 g or more, and they can be used throughout the first year of life. Not all premature infants need these formulas to grow appropriately. The AAP (2009a) suggests that the transitional formulas be continued until the infant's weight for length is maintained at greater than the 25th percentile, or up to 9 or 12 months corrected age. It is not clear which premature infants need this specialized formula as studies have not always demonstrated improved growth with the use of transitional formula (AAP, 2009b). Transitional formulas are available in powder form and in ready-to-feed form.

### Formula Adjustments

Occasionally it may be necessary to increase the energy content of the formulas fed to small infants. This may be appropriate when the infant is not growing quickly enough and is already consuming as much as possible during feedings.

### Concentration

One approach to providing hypercaloric formula is to prepare the formula with less water, thus concentrating all its nutrients, including energy. Concentrated infant formulas with energy contents of 24 kcal/oz are available to hospitals as ready-to-feed nursettes. However, when using these concentrated formulas, it is important to consider the infant's fluid intake and losses in relation to the renal solute load of the concentrated feeding to ensure that a positive water balance is maintained. This method of increasing formula density is often preferred because the nutrient balance remains the same; infants who need more energy also need additional nutrients. As mentioned, the transitional formulas are available in ready-to-feed and powder form and can be concentrated from 24 to 30 kcal/oz. However, this formula is still inadequate for infants who need additional calcium (e.g., infants with osteopenia).

A ready-to-feed 30 kcal/oz premature infant formula is available. It meets the nutritional needs for premature infants who must be fluid restricted because of illness. This 30 kcal/oz formula can be diluted with premature infant formula 24 kcal/oz to make 26, 27, or 28 kcal/oz milks (see Box 43-2). These milks are sterile and are the preferred source of providing concentrated milks to premature infants in the neonatal intensive care unit (NICU). Infant formula powder is not sterile and is not to be used with high-risk infants when a nutritionally adequate liquid, sterile product is available (Robbins and Beker, 2004).

### Caloric Supplements

Another approach to increasing the energy content of a formula involves the use of caloric supplements such as vegetable oil, MCT oil, or glucose polymers. These supplements increase the caloric density of the formula without markedly altering solute load or osmolality. However, they do alter the relative distribution of total calories derived from protein, carbohydrate, and fat. Because even small amounts of oil or carbohydrate dilute the percentage of calories derived from protein, adding these supplements to human milk or standard (20 kcal/oz) formulas is not advised. Caloric supplements should be used only when a formula already meets all nutrient requirements other than energy or when the renal solute load is a concern.

When a high-energy formula is needed, glucose polymers can be added to a base that has a concentration of 24 kcal/oz or greater (either full-strength premature formula or a concentrated standard formula), with a maximum of 50% of total calories from fat and a minimum of 9% of total calories from protein. Vegetable oil may be added

to a feeding or given as a oral medication. Vegetable oil added to a day's supply of formula will separate out from the milk and cling to the milk storage container, and will not be in the feeding to the infant. See Table 45-6.

## NUTRITION ASSESSMENT AND GROWTH

### Dietary Intake

Dietary intake needs to be evaluated to ensure that the nutrition provided meets the infant's needs. Parenteral fluids and milk feedings are advanced as tolerated, and the nutrient intakes must be reviewed to ensure that they are within the guidelines for premature infants and that the infant is thriving on the nutrition provided. Appropriate growth and growth charts are reviewed in the following paragraphs.

### Laboratory Indices

Laboratory assessments usually involve measuring the following parameters: (1) fluid and electrolyte balance, (2) PN or EN tolerance, (3) bone mineralization status, and (4) hematologic status (Table 43-15). Hemoglobin and hematocrit will be monitored as medically indicated. The early decrease in hematocrit reflects the physiologic drop in hemoglobin after birth and blood drawings for laboratory assessments. Early low hemoglobins are treated with blood transfusions if needed. Dietary supplementation will not change this early physiologic drop in hemoglobin.

### Growth Rates and Growth Charts

All neonates typically lose some weight after birth. Preterm infants are born with more extracellular water than term infants and thus tend to lose more weight than term infants.

However, the postnatal weight loss should not be excessive. Preterm infants who lose more than 15% of their birth weight may become dehydrated from the inadequate fluid intake or experience tissue wasting from poor energy intake. An infant's birth weight should be regained by the second or third week of life. The smallest and sickest infants take the longest time to regain their birth weights.

During the first 98 days of life the Ehrenkranz growth chart is commonly used to assess weight progress (Ehrenkranz et al., 1999) (Figure 43-3). This chart longitudinally depicts daily weight changes and actual growth curves for 1660 infants who were born with a weight of 501 to 1500 g ( $1\frac{1}{2}$  to  $3\frac{1}{2}$  lb). These infants received care in 12 different NICUs for various neonatal medical problems. Charts are also available for length, head circumference, and midarm circumference (see *Useful Websites* for a source to create a growth curve for an individual infant). These charts reflect how premature infants grow, and do not allow for the assessment of catch-up growth by the preterm infant.

Intrauterine growth curves have been developed using birth weight, birth length, and birth head circumference data of infants born at several successive weeks of gestation. The intrauterine growth curves are the standard of growth recommended for premature infants. During the first week of life premature infants fall away from their birth weight percentile, which reflects the normal postnatal weight loss of newborn infants. After an infant's condition stabilizes and the infant begins consuming all needed nutrients, the infant may be able to grow at a rate that parallels these curves. An intrauterine weight gain of 15 g/kg/day can be achieved.

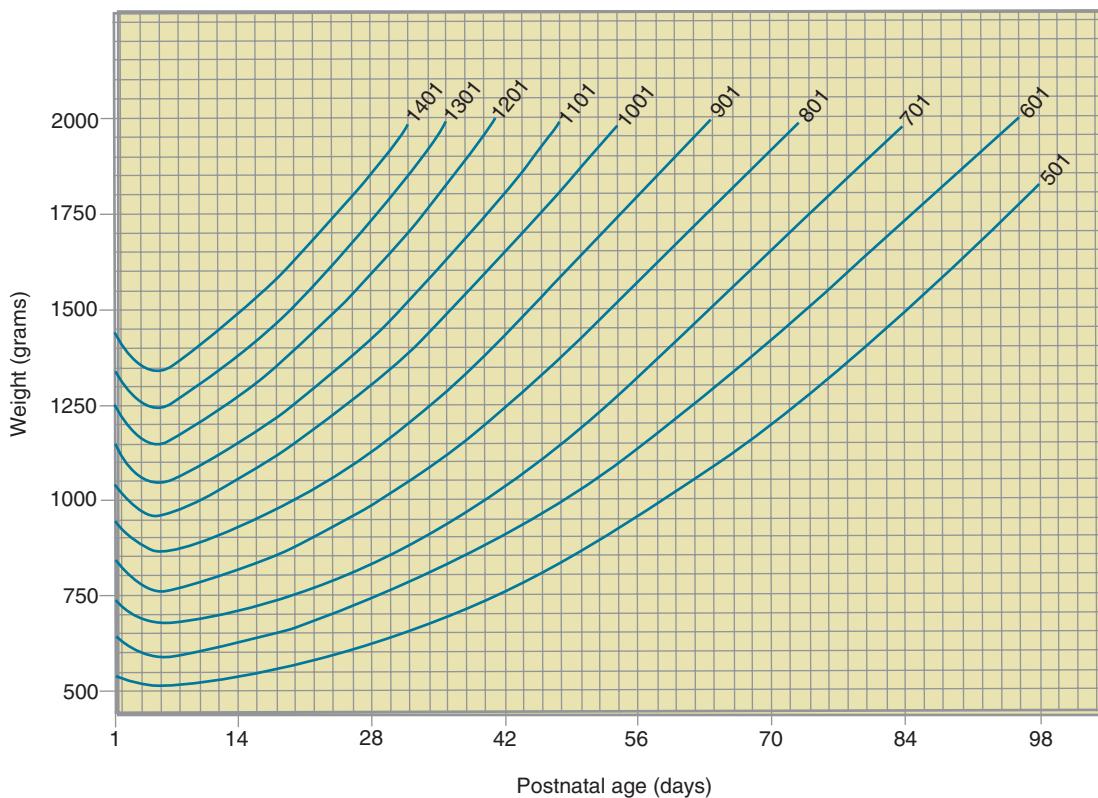

Although weight is an important anthropometric parameter, measurements of length and head circumference can also be helpful. A growth curve can be used to evaluate the

**TABLE 43-15**

**Monitoring of the Feeding of the Premature Infant**

Monitor	Parenteral Nutrition	Enteral Nutrition
Fluid & electrolyte balance	Fluid intake Urine output Daily weights Serum sodium, potassium and chloride Serum creatinine BUN	Fluid intake Urine output Daily weights
Glucose homeostasis	Serum glucose	Not routine
Fat tolerance	Serum triglycerides	Not indicated
Protein nutriture: BUN	Not helpful	Low levels with human milk-fed infants may indicate need for more protein
Osteopenia	Serum calcium Serum phosphorous	Serum calcium Serum phosphorous
Parenteral nutrition toxicity	Serum alkaline phosphatase activity Cholestasis: conjugated bilirubin Liver function: ALT	Serum alkaline phosphatase activity Not indicated

ALT, Alanine aminotransferase; BUN, blood urea nitrogen.

adequacy of growth in all three areas (Figure 43-4). This chart has a built-in correction factor for prematurity; the infant's growth can be followed from 22 to 50 weeks of gestation and it represents cross-sectional data from Canada, Sweden, Australia, and the United States (Fenton, 2003).

Additional intrauterine growth charts based on the birth-weight, birth length, and head circumferences of infants born in the United States have been developed (Olsen et al., 2010). Separate charts for male and female infants are available and infants can be plotted from 23 to 41 weeks' gestation.

The 2006 World Health Organization Growth Charts designed for children from birth to 2 years of age should also be used for preterm infants once they reach 40 weeks' gestation, as long as the age is adjusted (see *Focus On: Long-Term Outcome for Premature Infants*). For example, an infant born at 28 weeks of gestation is 12 weeks premature (40 weeks of term gestation minus 28 weeks of birth gestational age). Four months after birth, the growth parameters of a premature infant born at 28 weeks of gestation can be compared with those of a 1-month-old infant born at term (Box 43-3). When using growth grids, age should be adjusted for prematurity until at least 2½ to 3 years of corrected age. In Figure 43-5 A.R.'s pattern of growth is shown through 18 years of age. These charts are based on term, healthy infants who were breast-fed the first year of life (Grummer-Strawn et al., 2010). By using this chart, the infant's growth can be compared with the term infant to assess catch-up growth.

### BOX 43-3

#### Steps for Adjusting Age for Prematurity on Growth Charts

Calculate the number of weeks the infant was premature:

- 40 weeks (term) – birth gestational age = number of weeks premature
- The resulting number of weeks is the correction factor.
- Calculate the adjusted age for prematurity:
- Chronologic age – Correction factor = Adjusted age for prematurity

For example:

40 weeks – 28 weeks of gestation = 12 weeks premature

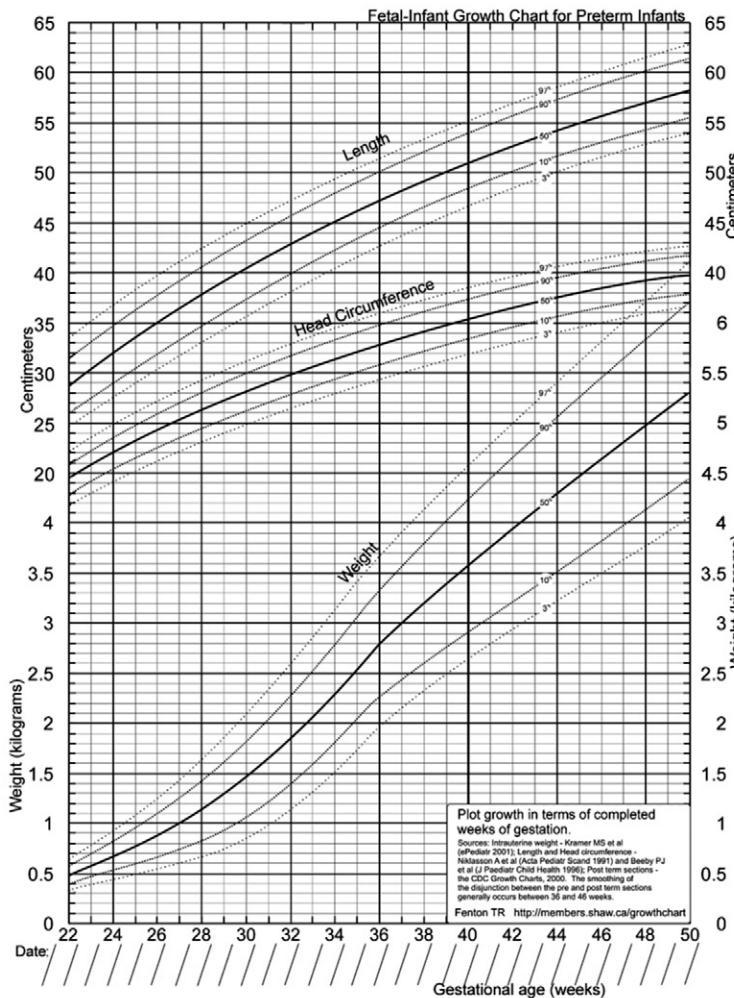

Therefore 12 weeks (3 months) is the correction factor.

4 months (chronologic age) – 3 months (correction factor) = 1 month adjusted age

### DISCHARGE CARE

Establishment of successful feeding is a pivotal factor determining whether a preterm infant can be discharged from the hospital nursery. Preterm infants must be able to (1) tolerate their feedings and usually obtain all of their feedings from the breast or bottle, (2) grow adequately

**FIGURE 43-4** Example of a growth record of weight, length, and head circumference for infants from 22 to 50 weeks of gestation. This chart has a built-in correction factor for prematurity. <http://members.shaw.ca/growthchart/> (From Fenton TR: A new growth chart for preterm babies: Babson and Benda's chart updated with recent data and a new format, *BMC Pediatr* 3:13, 2003.)

## © FOCUS ON

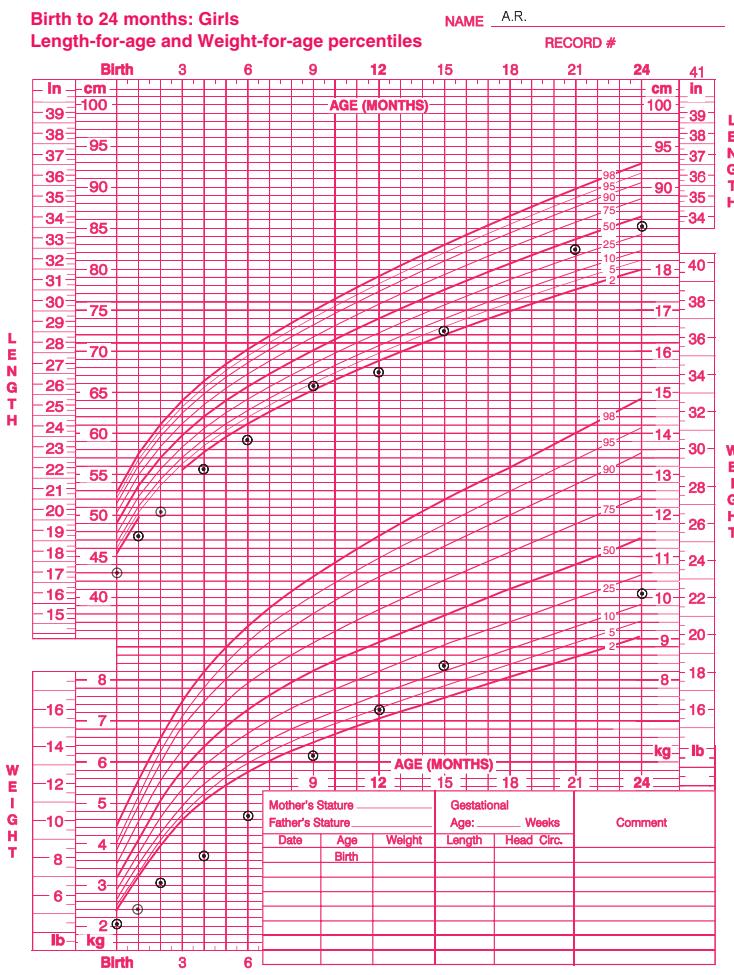

### Long-Term Outcome for Premature Infants

As the survival of premature infants continues to improve, their physical growth, mental development, health, and quality of life are being evaluated and investigated. Previously it was believed that, if premature infants experienced catch-up growth, it would occur only during the first few years of life. However, catch-up growth for weight, length, and head circumference can continue throughout childhood. As adults, premature infants tend to be shorter and weigh more than infants born at term (Doyle and Anderson, 2010). However, premature infants have normal heights and their heights may reflect their genetic potential.

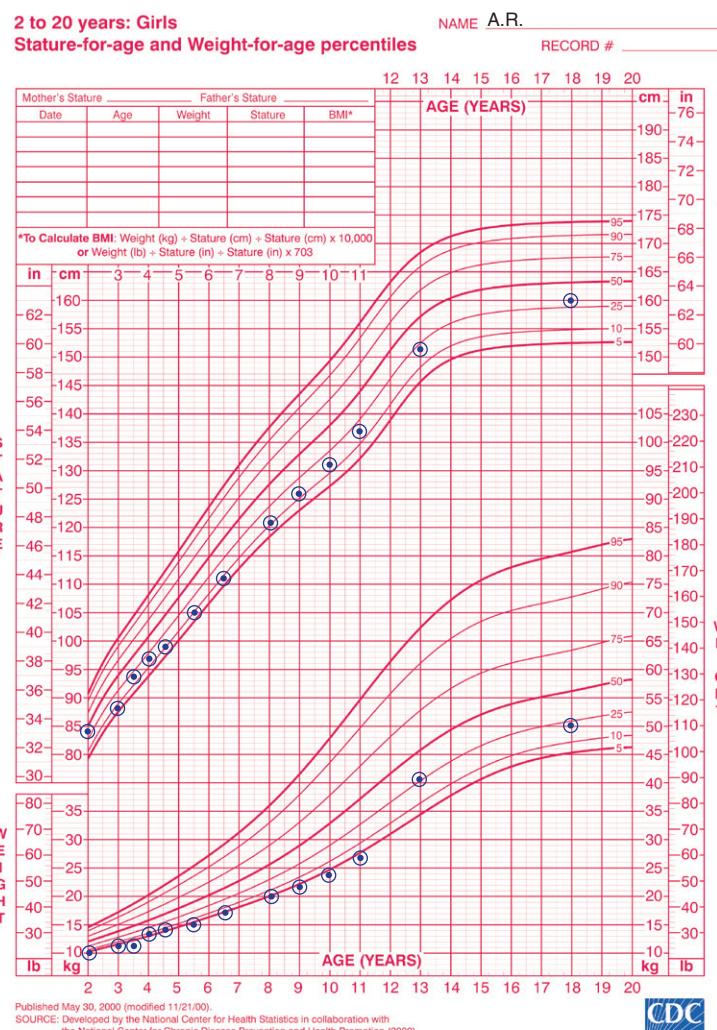

The premature infants' increase in body mass index may be a risk factor for type 2 diabetes. In adulthood, very low birthweight infants often have decreased glucose regulation as compared with infants born at term. Higher fasting insulin levels, impaired glucose tolerance, and increased insulin resistance may occur (Hovi et al., 2007). The extremely low birthweight (ELBW) infants have been reported to have higher blood pressures than infants born at term and normal weight (Doyle and Anderson, 2010).

Only recently have tools been developed and validated that assess how adults report their health status and quality of life. Saigal and colleagues (2006a, 2006b) compared two groups of adults at 23 years of age. The first group included 143 adults who were born prematurely with ELBW. The second group consisted of 130 adults who were born at term and were not low birthweight infants. All adults were interviewed in the same way except for seven adults who were severely neurologically impaired. Parents completed the evaluations for their children. The adults born ELBW reported more functional limitations in cognition, sensation, mobility, and self-care. However, there was no difference between the two groups in their mean self-reported, health-related quality of life. The two groups were similar in their level of education attainment, living on their own or with parents, marital status, and employment.

Therefore not only are more premature infants surviving, but they also are growing into adults who are enjoying and living productive lives (Doyle and Anderson, 2010; Hack, 2009). The medical and nutrition care in the hospital nursery continues to progress, which improves outcome in the nursery and sets the stage for later development.

A

B

**FIGURE 43-5** A, Graphs showing how A.R. (from Figure 43-2), who was born at 27 weeks of gestation, grew after leaving the neonatal unit 1 day before her due date at a weight of 4½ lb. Heights and weights until age of 24 months are plotted on the grid at “corrected age” points. A.R. experienced catch-up growth during the first 12 months. B, A.R.’s growth pattern from the age of 2 to 18 years. During the first 10 years she grew at the 5th percentile for weight and the 10th percentile for height. She followed her channel of growth but did not experience catch-up growth. However, between the ages of 10 and 13 she began to change growth channels and moved to the 25th percentile for weight and the 25th percentile for height (catch-up growth). At 18 years she crossed the 25th percentile for height and fell slightly below the 25th percentile for weight.

on a modified-demand feeding schedule (usually every 3 to 4 hours during the day for bottle-fed infants or every 2 to 3 hours for breast-fed infants), and (3) maintain their body temperature without the help of an incubator. Medically stable premature infants who have delayed feeding development will go home on gavage feedings for a short period. In addition, it is important that any ongoing chronic illnesses, including nutrition problems, be manageable at home.

Most important, the parents must be ready to care for their infant. In hospitals that allow parents to visit their infants in the nursery 24 hours a day, staff can help parents develop their caregiving skills and learn to care for their infant at home. Often, parents are permitted to “room in” with their infant (i.e., stay with the infant all day and night)

before discharge, which helps build confidence in their ability to care for a high-risk infant (Figure 43-6).

Many preterm infants who are discharged from the hospital weigh less than 5½ lb. Although these infants must meet certain discharge criteria before they can go home, the stress of a new environment may lead to setbacks. Small preterm infants should be followed very closely during the first month after discharge, and parents should be given as much information and support as possible. Within the first week of discharge, a home visit by a nurse, dietitian, or both and a visit to the pediatrician can be extremely helpful educationally; and they can provide opportunity for early intervention for developing problems.

Factors that affect the feeding skills and behavior of preterm infants are particularly important after the infants

**FIGURE 43-6** Family in the nursery with their premature infant.

have been discharged. Physical factors such as a variable heart rate, a rapid respiratory rate, and tremulousness are examples of physiologic events that interfere with feeding. In addition, infants weighing less than  $5\frac{1}{2}$  lb have poor muscle tone. Although muscle tone gradually improves as an infant becomes larger and more mature, it can deteriorate quickly in infants who are tired or weak. Feeding is often difficult for infants who have limited muscle flexion and strength and poor head and neck control, which are needed to maintain a good feeding posture. Positioning these infants in a manner that supports normal body flexion and ensures proper alignment of the head and neck during feedings is helpful. Premature infants may also need their chin and cheeks supported while bottle-feeding.

Small infants tend to sleep more than larger and term infants. It is much easier for preterm infants to feed effectively if they are fully awake. To awaken a preterm infant, the caregiver should provide one type of gentle stimulation for a few minutes and then change to a different type, repeating this pattern until the infant is fully awake. Lightly swaddling of the infant and then placing him or her in a semiupright position may also help.

The feeding environment should be as quiet as possible. Preterm infants are easily distracted and have difficulty focusing on feeding when noises or movements interrupt their attention. They also tire quickly and are easily overstimulated. When they are overstimulated, they may show only subtle signs of distress. It is important to teach parents of premature infants to recognize the subtle cues that indicate the need for rest or comfort and to respond to them appropriately.

After discharge, most preterm infants need approximately 180 mL/kg/day ( $2\frac{3}{4}$  oz/lb/day) of breast milk or standard

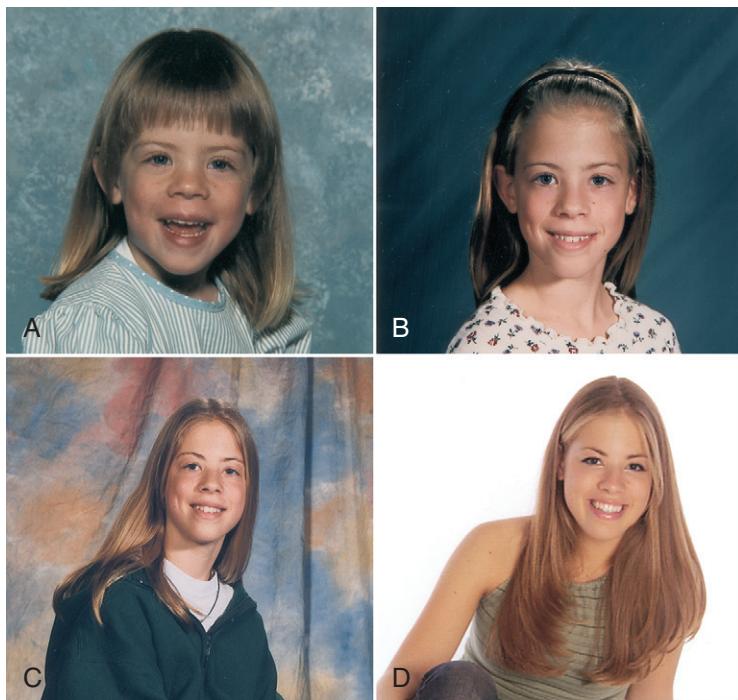

infant formula containing 20 kcal/oz. This amount of milk provides 120 kcal/kg/day (55 kcal/lb/day). Alternatively, transitional formula with a concentration of 22 kcal/oz can be provided at a rate of 160 mL/kg/day (or  $2\frac{1}{2}$  oz/lb/day). The best way to determine whether these amounts are adequate for individual infants is to compare their intake with their growth progress over time. Some infants may need a formula that provides 24 kcal/oz. As mentioned previously, powdered transitional formula can be readily altered to a concentration of 24 kcal/oz. The ready-to-feed premature formulas providing 24 kcal/oz are higher in most nutrients than are required postdischarge.

It is important to evaluate needs based on the three growth parameters: weight, length, and head circumference. Patterns of growth should be assessed to determine whether (1) individual curves at least parallel reference curves, (2) growth curves are shifting inappropriately across growth percentiles, (3) weight is appropriate for length, and (4) growth is proportionate in all three areas.

## NEURODEVELOPMENTAL OUTCOME

It is possible to meet the metabolic and nutritional needs of premature infants sufficiently to sustain life and promote growth and development. In fact, more tiny premature infants are surviving than ever before because of adequate nutrition support and the recent advances in neonatal intensive care technology. There is concern that the ELBW infant is often smaller at discharge than the infant of the same postmenstrual age who was not born prematurely. One report suggests that providing appropriate protein intake during week 1 of life to ELBW infants leads to improved growth of weight, length and head circumference at 36 weeks' gestation, and improved head circumference in male infants at 18 months' corrected age (Poindexter et al., 2006). Improved neurodevelopment and growth at 18 months has been reported with ELBW infants who gained more weight and had greater head circumference growth during their stay in the nursery (Ehrenkranz et al., 2006). The developmental outcome scores for ELBW infants have been higher as the intakes of human milk increase (Vohr et al., 2007).

The increased survival rate of ELBW infants has increased concerns about their short- and long-term neurodevelopmental outcomes. Many questions have been raised about the quality of life awaiting infants who receive neonatal intensive care. As a rule, VLBW infants should be referred to a follow-up clinic to evaluate their development and growth and begin early interventions (Wilson-Costello and Hack, 2006). The survival of ELBW infants has increased, with an increase in the number of children with neurodevelopmental disabilities, but also with an increase in the number of children who are developmentally normal (Wilson-Costello and Hack, 2006). Many of these premature infants reach adulthood with no evidence of any disability (Figure 43-7).

**FIGURE 43-7** The premature infant A.R. (see Figures 43-2 and 43-6) as she grows up. **A**, 3½ years. **B**, 10 years. **C**, 14 years. **D**, 18 years. (**D** Courtesy Yuen Lui Studio, Seattle, Wash.)

## CLINICAL SCENARIO 1

Sara, an infant born at 26 weeks of gestation, was admitted to the neonatal intensive care unit. Her birth weight was 850 g (appropriate for gestational age). Sara had respiratory distress syndrome and had to receive a tube for mechanical ventilation. During the first few hours of her life, she was given surfactant, and her ventilator settings were lowered. She was also placed in a humidified incubator and given 100 mL/kg/day of starter parenteral nutrition (dextrose 10% in water with amino acids) intravenously.

On the second day after her birth, she had gained 20 g, and her serum sodium concentration and urine volume output were low. She was diagnosed with a patent ductus arteriosus and was given indomethacin to close the ductus arteriosus.

On the fourth day after birth, her body weight had decreased 50 g—6% of her birth weight—and her serum electrolyte levels were normal. The protein concentration of her parenteral fluids was increased, as was the volume of intravenous fat being provided.

By the sixth day, Sara was clinically stable. She began receiving feedings of milk from her mother—0.7 mL every 2 hours (10 mL/kg of her birth weight)—via bolus oral gastric tube. The feedings were tolerated well. She then began receiving daily a larger volume of her mother's breast milk and less parenteral fluids. Full enteral feedings were estab-

lished, and following extubation Sara was successfully breathing on her own.

### Nutrition Diagnostic Statement, Day 2

Excessive fluid intake related to intravenous fluids as evidenced by gain of 20 g and low serum sodium level.

### Nutrition Diagnostic Statement, Day 6

Inadequate intake of protein and minerals related to need for human milk fortifier as evidenced by feeding only expressed breast milk.

### Nutrition Care Questions

1. On the second day after birth, should Sara's intravenous fluid volume have been (1) increased because she needed more calories, (2) decreased because she was overhydrated, or (3) changed to enteral feedings because she was clinically stable?
2. How should the intravenous fat that was given to Sara have been administered?
3. The breast milk from Sara's mother may have inadequate amounts of which nutrients? What do you recommend to resolve this?

## CLINICAL SCENARIO 2

Baby Jones was born at 29 weeks of gestation, and his birthweight was 1400 g. He is now 1 week old or 30 weeks' postmenstrual age and weighs 1375 g. He is receiving parenteral nutrition at 130 mL/kg/day that contains 12.5% dextrose and 3.5% amino acids and a 20% intravenous fat emulsion at 15 mL/kg per day. The registered dietitian assesses the nutrient intake, and calculations are given in the following table. The patient's intakes are compared with the parenteral guidelines of the American Academy of Pediatrics (AAP) (2009b) for premature infants.

NUTRIENT	NUTRIENT (KG/DAY)	GUIDELINES (KG/DAY)
Kilocalories kcal/kg/day	103	90-100
Glucose mg/kg/min	11.3	11-12
Protein g/kg	4.6	2.7-3.5
Fat g/kg	3	1-3

### Nutrition Diagnostic Statement

Excessive protein intake related to protein intake 4.6 g/kg/day as evidenced by intake greater than recommendation of 3.5 g of protein per kilogram established by the AAP in 2009.

### Nutrition Care Questions

1. The registered dietitian chooses the nutrition diagnosis and writes the problem-etiologic-signs and symptoms statement. Interventions include decreasing the amino acid concentration to 2.7%, which will provide 3.5 g of protein per kilogram per day.
2. Monitor and evaluate infant's nutrition status in how many days?
3. What guidance is needed for the staff to evaluate for signs of dehydration?

# Medical Nutrition Therapy for Genetic Metabolic Disorders

### KEY TERMS

argininosuccinic aciduria (ASA)

autosomal-recessive

branched-chain ketoaciduria or maple syrup urine disease (MSUD)

carbamyl-phosphate synthetase (CPS) deficiency

citrullinemia

galactosemia

genetic metabolic disorders

gluconeogenesis

glycogen storage diseases (GSDs)

glycogenolysis

ketone utilization disorder

L-carnitine

long-chain 3-hydroxyacyl-CoA dehydrogenase deficiency (LCHAD)

medium-chain acyl-CoA dehydrogenase deficiency (MCAD)

methylmalonic acidemia

ornithine transcarbamylase (OTC) deficiency

phenylketonuria (PKU)

propionic acidemia

**Genetic metabolic disorders** are inherited traits that result in the absence or reduced activity of a specific enzyme or cofactor. Most genetic metabolic disorders are inherited as **autosomal-recessive** traits; *autosomal* means that the gene is located on a chromosome other than the X or Y chromosomes. The treatment for many metabolic disorders is medical nutrition therapy (MNT), with medications specific to the disorder (e.g., phenylketonuria PKU). Here, the goals of MNT are to maintain biochemical equilibrium for the affected pathway, provide adequate nutrients to support typical growth and development, and support social and emotional development. Nutrition interventions are designed to circumvent the missing or inactive enzyme by (1) restricting the amount of substrate available, (2) supplementing the amount of product, (3) supplementing the enzymatic cofactor, or (4) combining any or all of these approaches. This chapter describes the primary conditions found more commonly in the United States. Table 44-1 outlines other disorders by the enzymatic defects, distinctive

clinical and biochemical features, and current approaches to dietary therapy.

In some instances, when treatment is initiated early in the newborn period and meticulously continued for a lifetime, the affected individual can be cognitively and physically normal. In conditions such as galactosemia, cognitive and physical damage can occur despite early and meticulous treatment. Biochemical disorders range from variations in enzyme activity that are benign, to severe manifestations that are incompatible with life. For many of them, significant questions related to diagnosis and treatment remain.

### NEWBORN SCREENING

Most inherited metabolic disorders are associated with severe clinical illness that often appears soon after birth. Intellectual disability and severe neurologic involvement

*Text continued on p. 1001*

**TABLE 44-1**  
**Selected Genetic Metabolic Disorders That Respond To Dietary Treatment**

Disorder	Affected Enzyme	Prevalence	Clinical and Biochemical Features	Medical Nutrition Therapy	Adjunct Treatment
Urea Cycle Disorders (UCDs)					
Carbamyl-phosphate synthetase deficiency	Carbamyl-phosphate synthetase	1:30,000 (all UCDs)	Vomiting, seizures, sometimes coma → death Survivors usually have ID ↑ plasma ammonia and glutamine	Food: low protein Formula: without nonessential amino acids	L-carnitine, phenylbutyrate,* L-citrulline, L-arginine Hemodialysis or peritoneal dialysis during acute episodes
Ornithine transcarbamylase deficiency	Ornithine transcarbamylase ( $\alpha$ -linked)	1:30,000 (all UCDs)	Vomiting, seizures, coma → death as a newborn ↑ plasma ammonia, glutamine, glutamic acid and alanine	Food: low protein Formula: without nonessential amino acids	L-carnitine, phenylbutyrate,* L-citrulline, L-arginine
Citrullinemia	Argininosuccinate synthetase	1:30,000 (all UCDs)	<i>Neonatal:</i> vomiting, seizures, coma → death <i>Infantile:</i> vomiting, seizures, progressive developmental delay ↑ plasma citrulline and ammonia, alanine	Food: low protein Formula: without nonessential amino acids	L-carnitine, phenylbutyrate,* L-arginine
Argininosuccinic aciduria	Argininosuccinate lyase	1:30,000 (all UCDs)	<i>Neonatal:</i> hypotonia, seizures <i>Subacute:</i> vomiting, FTT, progressive developmental delay ↑ plasma argininosuccinic acid, citrulline and ammonia	Food: low protein Formula: lower protein SF (without nonessential amino acids)	L-carnitine, phenylbutyrate*
Argininemia	Arginase	1:30,000 (all UCDs)	Periodic vomiting, seizures, coma Progressive spastic diplegia, developmental delay ↑ arginine and ammonia related to protein intake	Food: low protein Formula: lower protein SF (without nonessential amino acids)	L-carnitine, phenylbutyrate*

**TABLE 44-1****Selected Genetic Metabolic Disorders That Respond To Dietary Treatment—cont'd**

<b>Disorder</b>	<b>Affected Enzyme</b>	<b>Prevalence</b>	<b>Clinical and Biochemical Features</b>	<b>Medical Nutrition Therapy</b>	<b>Adjunct Treatment</b>
<b>Organic Acidemias</b>					
Methylmalonic acidemia	Methylmalonyl-CoA mutase or similar	1:80,000	Metabolic acidosis, vomiting, seizures, coma, often death ↑ organic urine acid and plasma ammonia levels	Food: low protein Formula: lower protein SF (without isoleucine, methionine, threonine, valine)	L-carnitine, vitamin B <sub>12</sub> IV fluids, bicarbonate during acute episodes
Propionic acidemia	Propionyl-CoA carboxylase or similar	1:80,000	Metabolic acidosis, ↑ plasma ammonia and propionic acid, ↑ urine methylcitric acid	Food: low protein Formula: lower protein SF (without isoleucine, methionine, threonine, valine)	L-carnitine, biotin IV fluids, bicarbonate during acute episodes
Isovaleric acidemia	Isovaleryl-CoA dehydrogenase	1:80,000	Poor feeding, lethargy, seizures, metabolic ketoacidosis, hyperammonemia	Food: low protein Formula: SF (without leucine)	L-carnitine, L-glycine
Ketone utilization disorder	2-methylacetoacetyl-CoA-thiolase or similar	Unknown	Vomiting, dehydration, metabolic ketoacidosis	Food: low protein Formula: SF (without isoleucine)	L-carnitine, Bicitra
Biotinidase deficiency	Biotinidase or similar	1:60,000	In infancy, seizures, hypotonia, rash, stridor, apnea; in older children, also see alopecia, ataxia, developmental delay, hearing loss	Avoid fasting, high complex carbohydrates	Supplemental oral biotin
<b>Carbohydrate Disorders</b>					
Galactosemia	Galactose-1-phosphate uridylyltransferase	1:50,000	Vomiting, hepatomegaly, FTT, cataracts, ID, often early sepsis ↑ urine and blood galactose	Eliminate lactose, low galactose, use soy protein isolate formula	
Hereditary fructose intolerance	Fructose-1-phosphate aldolase	estimated: 1:20,000	Vomiting; hepatomegaly; hypoglycemia, FTT, renal tubular defects after fructose introduction	No sucrose, fructose	
Fructose 1,6-diphosphatase deficiency	Fructose 1,6-diphosphatase	Unknown	↑ blood and urine fructose after fructose feeding	Hypoglycemia, hepatomegaly, hypotonia, metabolic acidosis upon fructose introduction	No sucrose, fructose
				No ↑ blood/urine fructose	

Glycogen storage disease, type Ia	Glucose-6-phosphatase	1:60,000	Profound hypoglycemia, hepatomegaly	Low lactose, fructose, sucrose; low fat; high complex carbohydrate; avoid fasting	Raw cornstarch, iron supplements
<b>Amino Acid Disorders</b>					
Hyperphenylalaninemas	Phenylalanine hydroxylase	1:15,000		Food: low protein Formula: SF (without Phe, supplemented with tyrosine)	
Mild phenylketonuria	Phenylalanine hydroxylase	1:24,000	↑ blood Phe	Food: low protein Formula: SF (without Phe, supplemented with tyrosine)	
Dihydropteridine reductase deficiency	Dihydropteridine reductase	Rare	↑ blood Phe Irritability, developmental delay, seizures	Food: low protein Formula: SF (without Phe, supplemented with tyrosine)	Biopterin, 5-hydroxytryptophan, L-dopa, folic acid
Biopterin synthase defect	Biopterin synthase	Rare	Mild ↑ blood Phe, irritability, developmental delay, seizures	None	l-dopa, tetrahydrobiopterin, 5-hydroxytryptophan Nitisinone <sup>†</sup>
Tyrosinemia, type I	Fumarylacetoacetate hydrolase	<1: 120,000	Vomiting, acidosis, diarrhea, FTT, hepatomegaly, rickets ↑ blood and urine tyrosine, methionine; ↑ urine parahydroxy derivatives of tyrosine; liver cancer	Food: low protein Formula: SF (without tyrosine, Phe, methionine)	
<b>Maple Syrup Urine Disease</b>					
MSUD	Branched-chain ketoacid decarboxylase complex (<2% activity)	1:200,000	Seizures, acidosis Plasma leucine, isoleucine, valine 10x normal	Food: low protein Formula: SF (without leucine, isoleucine, valine)	Thiamin <sup>†</sup>
Intermittent MSUD	Branched-chain ketoacid decarboxylase complex between episodes)	Rare	Intermittent symptoms Plasma leucine, isoleucine, valine 10x normal during illness	Food: low protein Formula: SF (without leucine, isoleucine, valine)	
Homocystinuria	Cystathione synthase or similar	1:200,000	Detached retinas; thromboembolic and cardiac disease; mild to moderate ID; bony abnormalities; fair hair and skin; ↑ methionine, homocysteine	Food: low protein Formula: SF (without methionine, supplemented with L-cystine)	Betaine, folate, vitamin B <sub>12</sub> , vitamin B <sub>6</sub> <sup>‡</sup> if folate levels are normal

<sup>§</sup>Use depends on clinic.

may be immediately apparent. Diagnosis of a specific disorder may be difficult, and appropriate treatment measures may be uncertain. Prenatal diagnosis is available for many metabolic disorders, but it usually requires the identification of a family at risk, which can be done only after the birth of an affected child. Effective newborn screening programs, as well as advanced diagnostic techniques and treatment modalities have improved the outcome for many of these infants.

Infants suspected of having a metabolic disorder should be afforded access to care offered by centers with expertise in treating these disorders. Infants who are afebrile for no apparent reason, lethargic, vomiting, in respiratory distress, or having seizures should be evaluated for an undiagnosed metabolic disorder. The initial assessment should include blood gas measurements, electrolyte values, glucose and ammonia tests, and a urine test for ketones.

Advances in newborn screening technology offer opportunities for earlier diagnosis, prevention of neurologic crisis, and improved intellectual and physical outcomes. When tandem mass spectrometry techniques are used in newborn screening laboratories, infants with a broader range of

metabolic disorders can be identified, and the disorder can be identified earlier (see *Focus On: Newborn Screening*). See Fig. 44-1.

## DISORDERS OF AMINO ACID METABOLISM

Nutrition therapy for amino acid disorders most commonly consists of substrate restriction, which involves limiting one or more essential amino acids to the minimum requirement while providing adequate energy and nutrients to promote typical growth and development (e.g., restricting phenylalanine [Phe] in phenylketonuria PKU). An inadequate intake of an essential amino acid is often as detrimental as excess. Supplementation of the product of the specific enzymatic reaction is usually required in nutrition therapy for amino acid disorders; for example, tyrosine (Tyr) is supplemented in formulas for treatment of PKU.

Requirements for individual amino acids are difficult to determine because typical growth and development can be achieved over a wide range of intake. The data of Holt and Snyderman (1967) are often used as the basis for prescribing

### © FOCUS ON

## Newborn Screening (NBS)

**S**ince the 1960s, states across the United States have adopted mandatory newborn screening (NBS) as law (Waisbren, 2006). These programs were developed as a result of the efficacy of the Guthrie bacterial inhibition assay, in which dried blood spots were assayed. This simple, sensitive, and inexpensive screening test became the basis for population-based screening systems for newborns. Hemoglobinopathies, endocrine disorders, metabolic disorders, and some infectious disorders can be effectively identified in this way.

In the 1990s tandem mass spectrometry began to be used in NBS and is now used across the United States (Therrell, 2006). This technology makes it possible to identify multiple disorders from dried blood spots. The number of disorders screened for varies widely by state, and expanded screening is also offered by private, for-profit companies. Follow-up programs also vary; some states have a centralized program, whereas follow-up in other states is less coordinated. Successful early NBS programs include screening for congenital hypothyroidism, phenylketonuria, congenital adrenal hyperplasia, galactosemia, sickle cell disease, and maple syrup urine disease (Broso et al., 2006).

The Maternal and Child Health Bureau (MCHB) of the U.S. Health Resources and Services Administration commissioned a report from the American College of Medical Genetics (ACMG). This expert panel identified 29 conditions for which newborn screening should be mandated and 25

secondary conditions that may be detected incidentally (MCHB, 2007). The ACMG developed a series of ACTion (ACT) sheets and confirmatory algorithms for disorders that are identified by NBS screening. The ACT sheets describe the steps health professionals should follow in communicating with the family and determining follow-up. They are available at [http://www.acmg.net/AM/Template.cfm?Section=NBS\\_ACT\\_Sheets\\_and\\_Algorithms\\_Table&Template=/CM/HTMLDisplay.cfm&ContentID=5649](http://www.acmg.net/AM/Template.cfm?Section=NBS_ACT_Sheets_and_Algorithms_Table&Template=/CM/HTMLDisplay.cfm&ContentID=5649).

Other groups, including the World Health Organization, March of Dimes, and Massachusetts Newborn Screening Advisory Committee, have also issued recommendations.

Providers who may be involved in the care and follow-up of families identified by NBS should have a good understanding of their state's system, as well as the factors that may affect results. Communication among families, primary health care providers, and tertiary clinics is critical to timely identification and treatment. Follow-up, including referral to the appropriate specialists, is important for any family who receives NBS test results. NBS fact sheets from the Committee on Genetics of the American Academy of Pediatrics describe (1) newborn testing; (2) follow-up of abnormal screening results to facilitate timely diagnostic testing and management; (3) diagnostic testing; (4) disease management, which requires coordination with the medical home and genetic counseling; and (5) continuous evaluation and improvement of the NBS system (Kaye et al., 2006).

**FIGURE 44-1** Tandem mass spectrometer. This technology makes screening for a broad range of metabolic disorders feasible. Blood levels of a number of organic acids are measured. (*Courtesy Washington State Newborn Screening Program.*)

amino acid intakes (Table 44-2). Careful and frequent monitoring is required to ensure the adequacy of the nutritional prescription. Although nitrogen studies are the most precise, weight gain in infants is a sensitive and easily monitored index of well being and nutrition adequacy.

### Phenylketonuria

**Phenylketonuria (PKU)** is the most common of the hyperphenylalaninemias. In this disorder phenylalanine is not metabolized to Tyr because of a deficiency or inactivity of phenylalanine hydroxylase as shown in Figure 44-2. Of the amino acid disorders, PKU provides a reasonable model for detailed discussion because it (1) occurs relatively frequently and most neonates are screened for it; (2) has a successful MNT treatment; and (3) has a predictable course, with available documentation of “natural” and “intervention” history (see *Focus On: Time Line of Events in the Diagnosis and Treatment of Phenylketonuria*).

Nutritional treatment involves restricting the substrate (Phe) and supplementing the product (Tyr) (see *Pathophysiology and Care Management Algorithm: Phenylketonuria*). Most affected infants exhibit phenylalanine hydroxylase deficiency; the remainder (less than 3%) have defects in associated pathways. Low phenylalanine nutrition therapy does not prevent the neurologic deterioration present in the disorders of associated pathways.

### Medical Treatment

All states have newborn screening programs for PKU and other metabolic disorders. Diagnostic criteria for PKU include blood concentrations of Phe that consistently exceed 6 to 10 mg/dL (360 to 600 mmol/L) and Tyr concentrations of less than 3 mg/dL (165 mmol/L). The diagnostic process should also include evaluation for hyperphenylalaninemia that results from the deficiency of enzymes other than phenylalanine hydroxylase. An effective newborn screening

program and access to an organized follow-up program are critical to early identification and treatment of infants with PKU.

The advantage of rigorous nutrition therapy has been demonstrated by measurements of intellectual function. Individuals who do not receive diet therapy have severe intellectual disability (mean intelligence quotient [IQ] of approximately 40), whereas individuals who are on therapy from the early neonatal period have normal IQs. Outcome, measured as intellectual function, depends on the age of the infant at diagnosis and start of nutrition therapy, as well as the individual's biochemical control over time.

Tetrahydrobiopterin (BH<sub>4</sub>) has been studied to evaluate its effectiveness as an alternative treatment to severe dietary Phe restriction. BH<sub>4</sub> is a cofactor needed for proper activity of the enzyme. Although supplementation with BH<sub>4</sub> holds promise as an adjunct therapy for some milder mutations, observations on long-term outcome are needed (Lee et al., 2005). Those individuals who respond have what is called *BH4-responsive PKU*. Other studies have examined the possibility of enzyme substitution with phenylalanine ammonia lyase to degrade Phe, or gene therapy to restore phenylalanine hydroxylase activity (Blau et al., 2010).

**Blood Phenylalanine Control.** Blood Phe concentration must be checked regularly, depending on the age and health status of the child, to be sure it remains within the range of 2 to 6 mg/dL or 120 to 360 mmol/L. Phe-containing foods are offered as tolerated as long as the blood concentration of Phe remains in the range of good biochemical control. The child's rate of growth and mental development must be carefully monitored.

Effective management requires a team approach in which the child, parents, registered dietitian, pediatrician, psychologist, social worker, and nurse work together to achieve and maintain biochemical control in an atmosphere promoting normal mental and emotional development. An essential

**TABLE 44-2****Approximate Daily Requirements for Selected Dietary Components and Amino Acids in Infancy and Childhood**

Dietary Component or Amino Acid	Age and Requirement	
	Birth to 12 mo (mg/kg)	1 to 10 yr (mg/day)
Phenylalanine	1-5 mo: 47-90 6-12 mo: 25-47	200-500*
Histidine	16-34	
Tyrosine <sup>†</sup>	1-5 mo: 60-80 6-12 mo: 40-60	25-85 (mg/kg)
Leucine	76-150	1000
Isoleucine	1-5 mo: 79-110 6-12 mo: 50-75	1000
Valine	1-5 mo: 65-105 6-12 mo: 50-80	400-600
Methionine <sup>‡</sup>	20-45	400-800
Cyst(e)ine <sup>§</sup>	15-50	400-800
Lysine	90-120	1200-1600
Threonine	45-87	800-1000
Tryptophan	13-22	60-120
Energy	1-5 mo: 108 kcal/kg 6-12 mo: 98 kcal/kg	70-102 kcal/kg
Water	100 ml/kg	1000 ml
Carbohydrate	kcal × 0.5 ÷ 4 = g/day	kcal × 0.5 ÷ 4 = g/day
Total protein	1-5 mo: 2.2 g/kg 6-12 mo: 1.6 g/kg	16-18
Fat	kcal × 0.35 ÷ 9 = g/day	kcal × 0.35 ÷ 9 = g/day

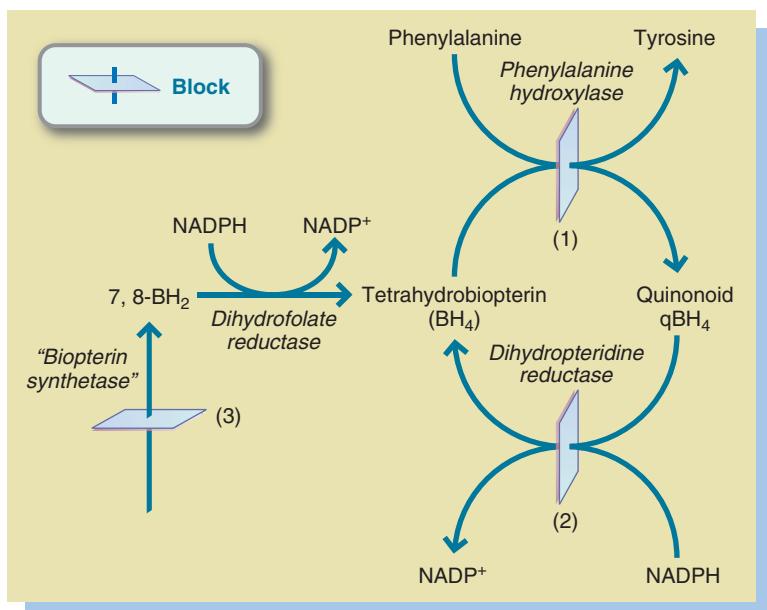

Modified from Committee on Nutrition, American Academy of Pediatrics: Special diets for infants with inborn errors of metabolism, *Pediatrics* 57:783, 1976. Compiled from amino acid data of Holt and Snyderman. Information on amino acid requirements of infants and children at different ages is limited; the figures given here are in excess of minimum requirements. Consequently, this table should be used only as a guide and should not be regarded as an authoritative statement to which individual patients must conform.

\*More phenylalanine (>800 mg) is required in the absence of tyrosine.

<sup>†</sup>Total phenylalanine plus tyrosine should be considered in the prescription because most phenylalanine is converted to tyrosine.

<sup>‡</sup>More methionine is required in the absence of cyst(e)ine.

<sup>§</sup>More cyst(e)ine is required in presence of a blocked *trans*-sulfuration outflow pathway for methionine metabolism.

## © FOCUS ON

### Time Line of Events in the Diagnosis and Treatment of Phenylketonuria

- 1934:** A. Folling identifies phenylpyruvic acid in the urine of mentally retarded siblings.
- 1950s:** G. Jervis demonstrates a deficiency of phenylalanine oxidation in the liver tissue of an affected patient. H. Bickel demonstrates that dietary phenylalanine restrictions lower the blood concentration of phenylalanine.
- 1960s:** R. Guthrie develops a bacterial inhibition assay for measuring blood phenylalanine levels.
- Mid-1960s:** Semisynthetic formulas restricted in phenylalanine content become commercially available.
- 1965-1970:** States adopt newborn screening programs to detect phenylketonuria (PKU).
- 1967-1980:** Collaborative Study of Children Treated for Phenylketonuria is conducted. Data from this study form the basis for treatment protocols for PKU clinics in the United States.
- Late-1970s:** Detrimental effects of maternal PKU are recognized as a significant public health problem.
- 1980s:** Lifelong restriction of phenylalanine intake becomes the standard of care in PKU clinics in the United States.
- 1983:** The Maternal PKU Collaborative Study begins to study the effects of treatment on the pregnancy outcome of women with phenylketonuria.

- 1987:** Techniques for carrier detection and prenatal diagnosis of PKU are developed.
- Late-1980s:** The gene for phenylalanine hydroxylase deficiency (MIM No. 261600) is located on chromosome 12q22-q24.1. Deoxyribonucleic acid mutation analysis can be accomplished with peripheral leukocytes.
- 1990s:** Phenylalanine level of 1-6 mg/dL (60-360 mmol/L), lower than the previous level of less than 10 mg/dL (600 mmol/L), becomes the new standard of care for treatment of PKU.
- 2000:** Tetrahydrobiopterin-responsive forms of PKU are recognized, especially those with mild mutations.
- 2010:** Continued research into alternative and adjunct therapies such as the use of large neutral amino acids, BH4 supplementation, enzyme substitution, and somatic gene therapy.

Data from Maternal Child Health Bureau: Newborn screening: toward a uniform screening panel and system, Genet Med 8(Suppl1):1S, 2006; Saugstad LF: From genetics to epigenetics, Nutr Health, 18:285, 2006; Mitchell JJ, Scriver CR: Phenylalanine hydroxylase deficiency. management tool for parents, children, and clinicians is the food diary used to monitor Phe intake. Daily record keeping supports compliance with treatment and builds self-management skills. An accurate record of food and formula intake for at least the 3 days before a laboratory specimen is obtained is mandatory for accurate interpretation of the results and subsequent adjustment of the Phe prescription.

Elevations in blood Phe concentration are generally caused by either excessive Phe intake or tissue catabolism. Intake of Phe in excess of the amount required for growth accumulates in the blood. Deficient energy intake or the stress of illness or infection can result in protein breakdown and the release of amino acids, including Phe, into the blood. In general, the anorexia of illness limits energy intake. Preventing tissue catabolism by maintaining intake of the formula/medical food as much as possible is essential. Although it may occasionally be necessary to offer only clear liquids during an illness, the Phe-free formula/medical food should be reintroduced as soon as it is feasible. It can be used as a tube feeding if oral intake is not possible.

The necessity of continuing the restricted-Phe dietary therapy beyond adolescence is a consideration. Progressively decreasing IQs, learning difficulties, poor attention span, and behavioral difficulties have been reported

in children who have discontinued the dietary regimen. Children who maintain well-controlled blood Phe levels demonstrate comparatively higher intellectual achievement than those who do not. Good dietary control of blood Phe concentrations is the best predictor of IQ, whereas “off-diet” blood Phe concentrations of greater than 20 mg/dL (1200 mmol/L) are the best predictors of IQ loss. Subtle deficits in higher-level cognitive function may persist even at blood Phe levels of 6 to 10 mg/dL (360 to 600 mmol/L); thus most clinics recommend treatment blood levels of 1 to 6 mg/dL (60 to 360 mmol/L). Restricted-Phe therapy should be continued for life to maintain normal cognitive function (Waisbren et al., 2007).

#### Medical Nutrition Therapy

**Formula.** For PKU dietary therapy is planned around the use of a formula/medical food with Phe removed from the protein. Formulas or medical foods provide a major portion of the daily protein and energy needs for affected infants, children, and adults. In general, the protein source in the formula/medical food is L-amino acids, with the critical amino acid (i.e., Phe) omitted. Carbohydrate sources are corn syrup solids, modified tapioca starch, sucrose, and hydrolyzed cornstarch. Fat is provided by a variety of oils.

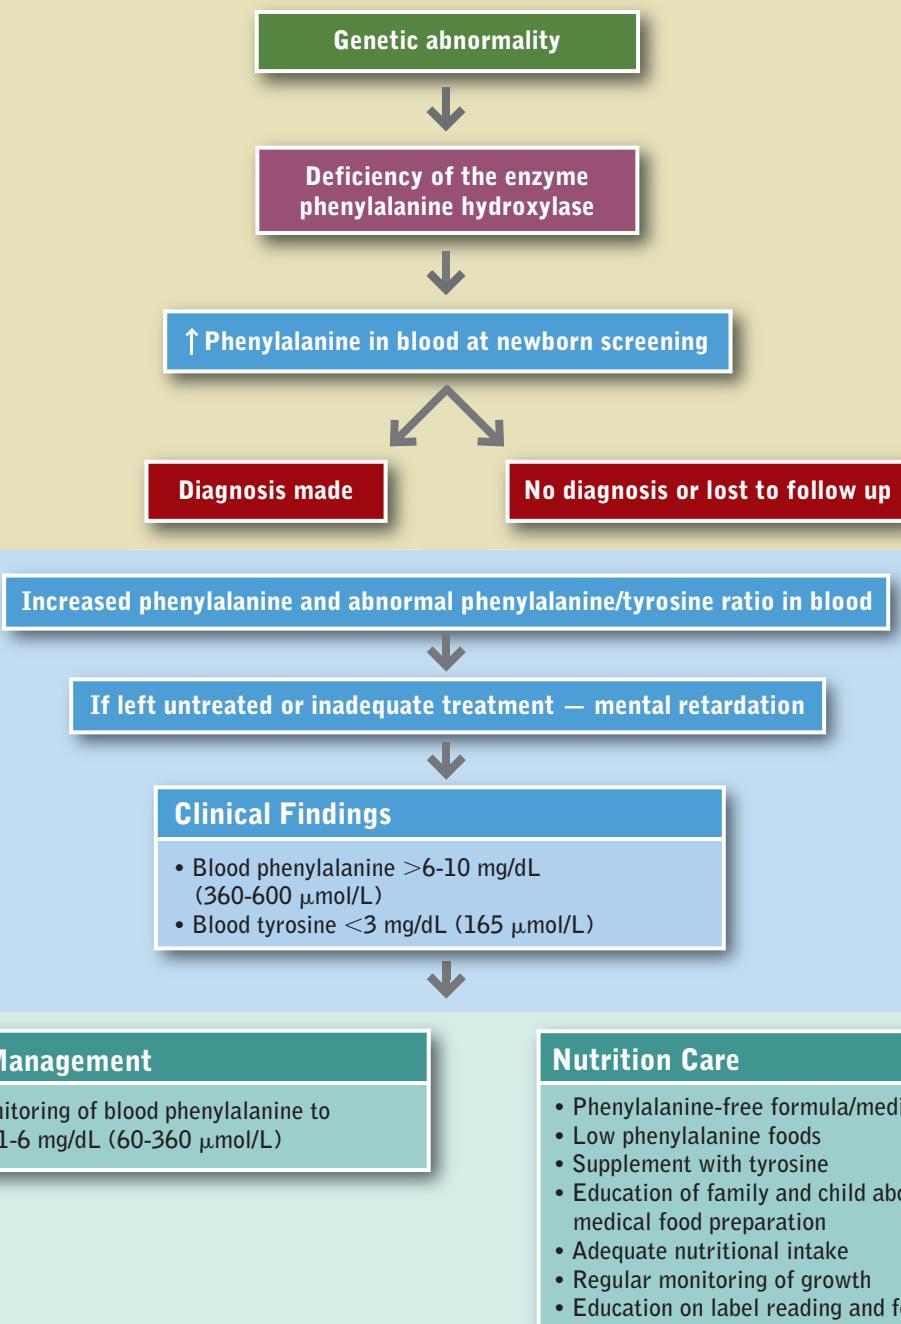

## PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

### Phenylketonuria

Etiology

Pathophysiology

Management

Some formula/medical foods contain no fat or carbohydrate; therefore these components must be provided from other sources. If prescribing formulas without fat, sources of essential fatty acids must be provided. Essential fatty acid deficiencies have been noted among individuals consuming fat-free formulas (Cleary et al., 2006; Rose, et al., 2005). Most formulas and medical foods contain calcium, iron, and

all other necessary vitamins and minerals and are a reliable source of these nutrients. When others are devoid of these nutrients, supplementation is needed to ensure nutritional adequacy.

Phe-free formula is supplemented with regular infant formula or breast milk during infancy and cow's milk in early childhood to provide high-biologic value protein,

nonessential amino acids, and sufficient Phe to meet the individualized requirements of the growing child. The optimal amount of protein substitute depends on the individual's age (and thus requirements for growth) and enzyme activity; thus it must be individually prescribed. Because the protein in specialized formulas is synthetic, it is provided in amounts greater than the Dietary Reference Intake (DRI).

The Phe-free formula and milk mixture should provide approximately 90% of the protein and 80% of the energy needed by infants and toddlers. A method for calculating the appropriate quantities of a Phe-free formula is shown in Table 44-3. It must be stressed that calculations should provide adequate but not excessive energy for the infant, as well as appropriate fluid to maintain hydration. To support metabolic control effectively, formula/medical foods must

**TABLE 44-3****Guidelines for Low-Phenylalanine Food Pattern Calculations****Case Study**

Molly is a 6-month-old infant with phenylketonuria.

**Baseline Data**

Age	6 mo
Weight (kg)	7.7
Weight percentile	50th
Height (cm)	67.8
Length percentile	50th
Head circumference (cm)	43.3
General health	Good
Activity	Very active

Step 1 Calculate the child's requirement for phenylalanine, protein, and energy (kcal) by using the information in Table 44-2.

## A. Phenylalanine

$$7.7 \text{ kg body weight} \times 60^* \text{ mg phenylalanine/kg/day} = 462 \text{ mg phenylalanine/day}$$

## B. Protein

$$7.7 \text{ kg body weight} \times 3.3^{\dagger} \text{ g protein/kg/day} = 25.4 \text{ g protein/day}$$

## C. Energy

$$7.7 \text{ kg body weight} \times 115^{\ddagger} \text{ kcal/kg/day} = 885 \text{ kcal/day}$$

Step 2 Determine the amount of phenylalanine-free formula required per day. This information is determined from the infant's protein requirement.

For example, 25.4 g of protein per day  $\times$  90% of protein from phenylalanine-free formula powder (Phenex-1) = 23 g of protein = 145 g of formula powder per day.

Step 3 Determine the amount of standard infant formula to be included in the formula.

Step 4 Determine the amounts of phenylalanine, protein, and energy in the phenylalanine-free and infant formulas as shown in the following examples.

Step 5 Determine the amount of water to mix with the phenylalanine-free formula. The consistency of the formula will vary according to the infant's age and fluid requirements. For example, to prepare formula for the infant described in the case study, mix 145 g of Phenex-1 and 120 g of Enfamil powder with 4 oz of water to prevent lumps from forming. Then add water to make a total of 32 oz of formula. This provides 4 bottles of 8 oz each.

Formula	Phenylalanine (mg)	Protein (g)	Energy (kcal)
Phenex-1 powder (145 g)		23.0	695
Enfamil powder (120 g)	410	4.8	120
<b>TOTAL</b>	<b>410</b>	<b>27.8</b>	<b>815</b>
Step 6 Determine the amount of phenylalanine, protein, and energy to be obtained from foods other than the formula mixture.			
Total phenylalanine		462 mg/day	
Phenylalanine in formula		410 mg/day	
Phenylalanine from other foods		52 mg/day	
Total protein		25.4 g/day	
Protein in formula		27.8 g/day	

**TABLE 44-3****Guidelines for Low-Phenylalanine Food Pattern Calculations—cont'd**

<b>Formula</b>	<b>Phenylalanine (mg)</b>	<b>Protein (g)</b>	<b>Energy (kcal)</b>
Protein from other foods		1-2 g/day	
Total energy		885 kcal/day	
Energy in formula		815 kcal/day	
Energy from other foods		70 kcal/day	
Step 7 Determine the amount of foods other than formula to be included in the dietary plan <sup>‡</sup>			
	<b>Phenylalanine (mg)</b>	<b>Protein (g)</b>	<b>kcal</b>
Baby rice cereal, 1 Tbsp	9	0.2	9
Green beans, strained, 1 Tbsp	9	0.2	4
Banana, mashed, 50 g	22	0.6	44
Carrots, strained, 3 Tbsp	9	0.3	12
<b>TOTAL</b>	<b>49</b>	<b>1.3</b>	<b>69</b>
Step 8 Determine the actual amounts of phenylalanine, protein, and energy per kilogram of body weight by dividing the total available nutrients by the body weight (in kg).			
Phenylalanine (mg)			
460 mg of phenylalanine $\div$ 7.7 kg body weight = 60 mg of phenylalanine per kilogram per day			
Protein 29.1 g of protein $\div$ 7.7 kg body weight = 3.8 g protein per kilogram per day			
Energy			
885 kcal $\div$ 7.7 kg of body weight = 115 kcal per kilogram per day			

\*A phenylalanine intake of 60 mg/kg/day is chosen as a moderate intake level. The prescription for phenylalanine must be adapted to individual needs as judged by growth and blood levels.

<sup>†</sup>Although these intakes are higher than the recommended dietary allowance, they are the intakes found by the Collaborative Study to promote normal growth with consumption of protein hydrolysate-based formula (Acosta, 1996).

<sup>‡</sup>Total energy intake must be adjusted to meet individual needs, and an excess must be avoided.

be consumed in three or four nearly equal portions throughout the day.

**Low-Phenylalanine Foods.** Foods of moderate- or low-Phe content are used as a supplement to the formula or medical food mixture. These foods are offered at the appropriate ages to support developmental readiness and to meet energy needs. Puréed foods from a spoon might be introduced at 5 to 6 months of age, finger foods at 7 to 8 months, and the cup at 8 to 9 months, using the same timing and progression of texture recommended for typical children. Table 44-4 suggests typical low-Phe food patterns for young children.

Low-protein pastas, breads, and baked goods made from wheat starch add variety to the food pattern and allow children to eat some foods “to appetite.” A variety of low-protein pastas, rice, baked goods, egg replacers, and other foods are available. Wheat starch and a variety of low-protein baking mixes for breads, cakes, and cookies are also available. Table 44-5 compares low-protein and regular food items.

In many cases parents create recipes or adapt family favorites to meet the needs of their children. These recipes offer the children a variety of textures and food choices, allowing them to participate in family meals. Families are also able to meet the energy and Phe needs of their children

without resorting to excessive intakes of sugars and concentrated sweets.

A formula or medical food that is free of Phe and has a more appropriate amino acid, vitamin, and mineral composition for an older child is generally introduced in the toddler or preschool period. The criteria for introduction of the “next-step” formulas are that the child accept the food pattern and formula well and reliably consume a wide variety of foods from the low-Phe food list. Successful management with consistently low blood Phe levels is based on habit (i.e., the formula/medical food is offered and consumed without negotiation or threat). Children respond favorably to the regularity of the time of ingestion of the formula/medical food and the familiarity of its taste and presentation. Table 44-6 compares a restricted Phe food pattern with a typical food pattern for a child of the same age.

**Education about Therapy Management.** The energy needs and amino acid requirements of children with PKU do not differ appreciably from those of children in general. With proper management, typical growth can be expected (Figure 44-3). However, parents may tend to offer excessive energy as sweets because they feel the child is being deprived of food experiences. Health care providers should support families in recognizing that children with PKU are healthy children who must make careful food

**TABLE 44-4****Typical Menus for a 3-Year-Old With Phenylketonuria**

Tolerance: 300 mg of phenylalanine/day Formula/medical food for 24 hours: 100 g of Phenyl-Free-2, 125 g of 2% milk, water to 34 oz This formula mixture provides 25.8 g of protein, 670 kcal of energy, 200 mg of phenylalanine.	Tolerance: 400 mg of phenylalanine/ day Formula/medical food for 24 hours: 100 g of Phenyl-Free-2, 125 g of 2% milk, water to 34 oz This formula mixture provides 25.8 g of protein, 670 kcal of energy, 200 mg of phenylalanine.

PKU, Phenylketonuria.

choices for themselves, not chronically ill children who require food indulgences.

Appropriate clinical interaction with family members provides them with the information and skills to differentiate between food behaviors that are typical for the age and developmental level of the child and those related specifically to PKU (Ievers-Landis et al., 2005). To avoid power struggles and conflicts over food, it is advisable to involve the child in choosing appropriate foods at an early age. Children who are 2 to 3 years old can master the concept of appropriate choices when foods are categorized as “yes foods” and “no foods.” The concept of an appropriate quantity of a food can be introduced to a 3- or 4-year-old child in terms of “how many” by counting crackers or raisins and then in terms of “how much” by weighing or measuring foods such as cereal or fruit. The child then moves to more complex tasks (e.g., formula and food preparation) and planning of meals (e.g., breakfast or a packed lunch). Responsibility for planning a full day’s menu by calculating the quantity of Phe in portions of food and compiling the daily total is the ultimate goal. These age-related tasks are shown in Table 44-7.

**Psychosocial Development.** The necessity of carefully controlling food intake may prompt parents to overprotect their children and perhaps to restrict their social activities. The children, in turn, may react negatively to their parents and to their nutrition therapy. The ability of the family to respond to the stresses of PKU, as reflected by adaptability

and cohesion scores, is demonstrated by improved blood Phe concentrations and the positive coping behaviors of older children with PKU. Thus continuing nutrition therapy beyond early childhood requires that children become knowledgeable about and responsible for managing their own food choices. The health care team becomes responsible for working with families and children to provide strategies that enable children and adolescents to participate in social and school activities, interact with peers, and progress through the typical developmental stages with self-confidence and self-esteem (Ievers-Landis et al., 2005).

Children require parental and professional support as they assume responsibility for their food management. Self-management of food choices is a strategy to prevent the child using dietary noncompliance as a wedge against parental restrictions. Normal intellectual development is a laudable goal of management of PKU, but to be entirely successful children with PKU concomitantly need to develop self-assurance and a strong self-image. This can be achieved in part by fostering self-management, problem-solving skills, independence, and a typical lifestyle.

**Maternal PKU**

A pregnant woman with elevated blood Phe concentrations endangers her fetus because of the amplified transport of amino acids across the placenta. The fetus is exposed to approximately twice the Phe level contained in normal maternal blood. Babies whose mothers have elevated blood

**TABLE 44-7****Tasks Expected of Children with Phenylketonuria by Age Level**

Age (yr)	School Level	Task
2-3	Preschool	Distinguishing between “yes” and “no” foods
3-4	Preschool	Counting: how many?
4-5	Preschool	Measuring: how much?
5-6	Kindergarten	Preparing own formula; using scale
6-7	Grade 1-2	Writing basic notes in food diary
7-8	Grade 2	Making some decisions on after-school snack
8-9	Grade 3	Preparing breakfast
9-10	Grade 4	Packing lunches
10-14	Middle school	Managing food choices with increasing independence
14-18	High school	Independently managing phenylketonuria

**TABLE 44-8****Frequency of Abnormalities in Children Born to Mothers with Phenylketonuria**

Complication (% of Offspring)	Maternal Phenylalanine Levels (mg/dL)				
	20	16-19	11-15	3-10	Non-PKU Mother
Mental retardation	92	73	22	21	5.0
Microcephaly	73	68	35	24	4.8
Congenital heart disease	12	15	6	0	0.8
Low birth weight	40	52	56	13	9.6

Modified from Lenke RR, Levy HL: Maternal phenylketonuria and hyper-phenylalaninemia: an international survey of the outcome of untreated and treated pregnancies, *N Engl J Med* 303:1202, 1980.

PKU, Phenylketonuria

Phe concentrations have an increased occurrence of cardiac defects, retarded growth, microcephaly, and intellectual disability, as presented in Table 44-8. The fetus appears to be at risk of damage even with minor elevations in maternal blood Phe levels, and the higher the level, the more severe the effect. Strict control of maternal Phe levels before conception and throughout pregnancy offers the best opportunity for normal fetal development (Koch et al., 2010).

Nutrition management for pregnant women with hyperphenylalaninemia is complex. The changing physiology of pregnancy and fluctuating nutritional needs are difficult to monitor with the precision required to maintain appropriately low blood-Phe concentrations. Even with meticulous attention to Phe intake, blood concentrations, and the nutritional requirements of pregnancy, a woman cannot be assured of a normal infant (Lee et al., 2005). The risks of abnormal development of the fetus, even with therapeutic dietary management and maintenance of blood Phe concentrations at 1 to 5 mg/dL (60 to 300 mmol/L), are an important consideration for young women with PKU considering pregnancy (Waisbren and Azen, 2003).

Nutritional management during pregnancy is challenging, even for women who have consistently followed a

low-Phe dietary regimen since infancy. Women who have discontinued Phe dietary treatment find that reinstating medical food consumption and limiting food choices can be difficult and overwhelming. Inadequate maternal nourishment (i.e., inadequate intakes of total protein, fat, and energy) may contribute to poor fetal development and should be avoided. Adherence to nutrition therapy during pregnancy for even the well-motivated woman requires family and professional support, as well as frequent monitoring of biochemical and nutritional aspects of both pregnancy and PKU.

### Adults Living with Phenylketonuria

Many adults with PKU have had the benefits of early diagnosis and treatment and are less likely to be affected by neurologic damage. However, among those who have had some degree of intellectual disability, hyperactivity and self-abuse are often major concerns. Not all patients have responded to late initiation of treatment with improved behavioral or intellectual function. For the difficult-to-manage older patient, a trial of a low-Phe food pattern is recommended. If successful, continued Phe restriction therapy may facilitate behavioral management.

Reinstituting a Phe-restricted food pattern is difficult after the eating pattern has been liberalized. However, the current recommendation of most clinics is effective management of blood Phe concentration throughout a lifetime. This recommendation is based on reports of declining intellectual capabilities and changes in the brain after prolonged, significant elevation of Phe concentrations (Waisbren and Azen, 2003). The efficacy of continued treatment throughout adulthood has been documented by reports of improved intellectual performance and problem-solving abilities when blood Phe levels are kept low. Dietary management of PKU throughout the life span is similar to that of other chronic disorders, and prudent MNT results in a normal quality of life (Bosch et al., 2006).

### Maple Syrup Urine Disease

**Maple syrup urine disease (MSUD)**, or **branched-chain ketoaciduria**, results from a defect in enzymatic activity, specifically the branched chain  $\alpha$ -ketoacid dehydrogenase complex. It is an autosomal-recessive disorder. Infants appear normal at birth, but by 4 or 5 days of age they demonstrate poor feeding, vomiting, lethargy, and periodic hypertonia. A characteristic sweet, malty odor from the urine and perspiration can be noted toward the end of the first week of life.

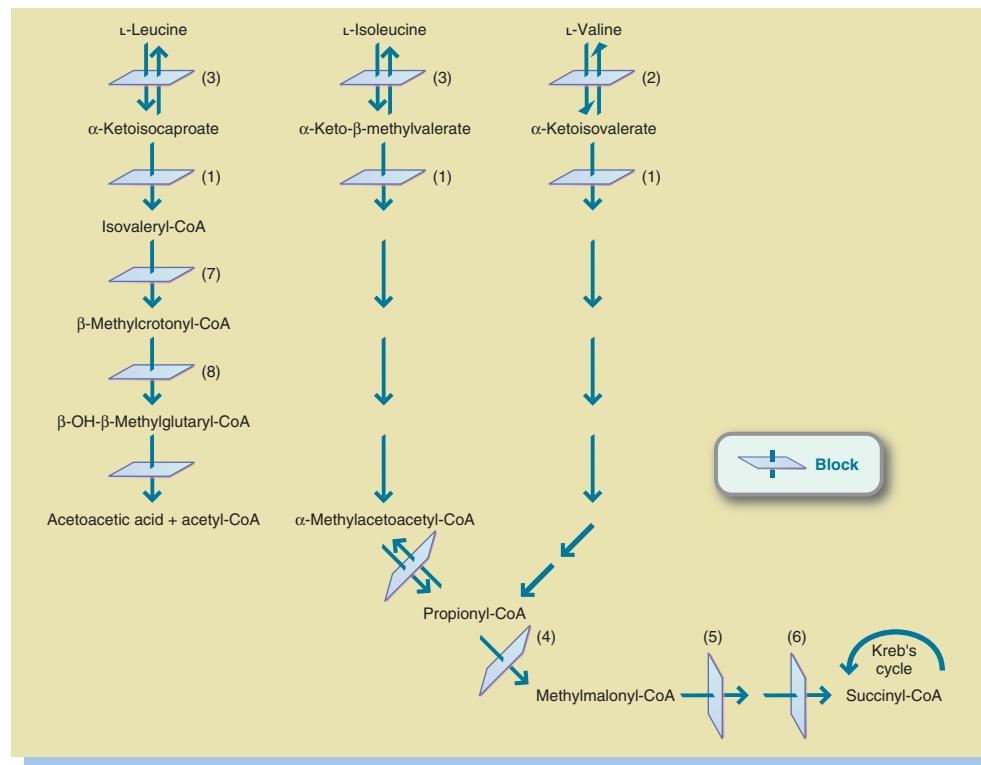

### Pathophysiology

The decarboxylation defect of MSUD prevents metabolism of the branched-chain amino acids (BCAAs) leucine, isoleucine, and valine (Figure 44-4). Leucine tends to be more problematic than the others. The precise mechanism for the complete decarboxylase reaction and the resultant neurologic damage is not known. Neither is the reason why leucine metabolism is significantly more abnormal than that of the other two BCAAs.

### Medical Treatment

Failure to treat this condition leads to acidosis, neurologic deterioration, seizures, and coma, proceeding eventually to death. Management of acute disease often requires peritoneal dialysis and hydration (see Chapter 36).

Depending on the severity of the enzyme defect, early intervention and meticulous biochemical control can provide a more hopeful prognosis for infants and children with MSUD. Reasonable growth and intellectual development in the normal-to-low-normal range have been described. Diagnosis before 7 days of age and long-term metabolic control are critical factors in long-term normalization of intellectual development. Maintenance of plasma leucine concentrations in infants and preschool children should be

**FIGURE 44-4** Organic acidemias and maple syrup urine disease (MSUD). **1**, Branched-chain ketoacid decarboxylase (MSUD); **2**, Valine aminotransferase; **3**, Leucine-isoleucine aminotransferase; **4**, Propionyl-CoA carboxylase (propionic acidemia); **5**, Methylmalonyl-CoA racemase (methylmalonic aciduria); **6**, Methylmalonyl-CoA mutase (methylmalonic aciduria); **7**, Isovaleryl-CoA dehydrogenase (isovaleric acidemia); **8**,  $\beta$ -methylcrotonyl-CoA carboxylase (biotin-responsive multiple carboxylase deficiency). CoA, Coenzyme A.

as close to physiologically normal as possible (Hoffman, 2006). Concentrations above 10 mg/dL (760 mmol/L) are often associated with  $\alpha$ -ketoacidemia and neurologic symptoms.

Because the liver is the central site of metabolic control for amino acids and other compounds that cause acute degeneration of the brain during illness, therapeutic liver transplantation has been proposed as an option in MSUD. Studies are underway to assess the long-term effects of this procedure on stabilization of biochemical and neurologic status (Strauss et al., 2006).

### Medical Nutrition Therapy

Nutrition therapy requires very careful monitoring of blood concentrations of leucine, isoleucine, and valine as well as growth and general nutritional adequacy. Several formulas specifically designed for the treatment of this disorder are available to provide a reasonable amino acid and vitamin mixture. These are generally supplemented with a small quantity of standard infant formula or cow's milk to provide the BCAAs needed to support growth and development. Some infants and children may require additional supplementation with L-valine or L-isoleucine to maintain biochemical balance.

BCAAs may be introduced gradually into the diet when plasma leucine concentrations are sufficiently decreased (Chuang and Shih, 2010). Clinical relapse is most often related to the degree of elevation of leucine concentrations, and these relapses often are related to infection. Acute infections represent life-threatening medical emergencies in this group of children. If the plasma leucine concentration increases rapidly during illness, BCAAs should be removed from the diet immediately and intravenous therapy started.

## DISORDERS OF ORGANIC ACID METABOLISM

### Organic Acid Disorders

The organic acid disorders are a group of disorders characterized by the accumulation in the blood of nonamino acid organic acids. Most of the organic acids are efficiently excreted in the urine. Diagnosis is based on excretion of compounds not normally present or the presence of abnormally high amounts of other compounds in the urine. The clinical course can vary but is generally marked by vomiting, lethargy, hypotonia, dehydration, seizures, and coma. Survivors often have permanent neurologic damage.

### Pathophysiology

**Propionic acidemia** is a defect of propionyl-coenzyme A (CoA) carboxylase in the pathway of propionyl-CoA to methylmalonyl-CoA, as illustrated in Figure 44-4. Metabolic acidosis with a marked anion gap and hyperammonemia is characteristic. Long-chain ketonuria may also be present.

At least five separate enzyme deficiencies have been identified that result in **methylmalonic acidemia** or aciduria. The

defect of methylmalonyl-CoA mutase apoenzyme is the most frequently identified. In methylmalonic academia, the clinical features are similar to those of propionic acidemia. Acidosis is common, and diagnosis is confirmed by the presence of large amounts of methylmalonic acid in blood and urine. Other findings include hypoglycemia, ketonuria, and elevation of plasma ammonia and lactate levels.

**Ketone utilization disorders** (mitochondrial 2-methylacetoacetyl-CoA thiolase deficiency or similar enzyme defect) are disorders of isoleucine and ketone body metabolism. Affected individuals are usually older infants or toddlers who present with ketoacidosis, vomiting, and lethargy with secondary dehydration and sometimes coma. This event often is preceded by febrile illness or fasting.

### Medical Treatment

Some patients with propionic acidemia may respond to pharmacologic doses of biotin. Long-term outcome in propionic acidemia is variable; hypotonia and cognitive delay may result even in children who are diagnosed early and who receive rigorous treatment. Liver damage and cardiomyopathy are possible sequelae. Liver transplantation may limit intellectual disability and cardiac changes (de Baulny et al., 2005).

Methylmalonic acidemia patients may respond to pharmacologic doses of vitamin B<sub>12</sub>. Responsiveness should be determined as part of the diagnostic process (Venditti, 2007). Progressive renal insufficiency is often a long-term outcome. Developmental delay is often caused by early and prolonged hyperammonemia.

For ketone utilization use disorders, the treatment is dietary protein restriction (usually 1.5 g/kg of body weight per day); supplementation with **L-carnitine**, a carrier of fatty acids across the mitochondrial membranes; avoidance of fasting by providing small, frequent meals that consist primarily of complex carbohydrates; and the use of Bicitra (sodium citrate-citric acid) to treat ketoacidosis.

### Medical Nutrition Therapy

The goals of managing acute episodes of propionic acidemia and methylmalonic acidemia are to achieve and maintain normal nutrient intake and biochemical balance. Maintenance of energy and fluid intake is important to prevent tissue catabolism and dehydration. Intravenous fluids correct electrolyte imbalances, and abnormal metabolites are removed through urinary excretion, promoted by a high fluid intake. Relapses of metabolic acidosis may result from excessive protein intake, infection, constipation, or unidentified factors. Parents become skilled at identifying early signs of illness. Treatment for these episodes must be rapid because coma and death can occur quickly.

Restricted protein intake is an essential component of the treatment of organic acid disorders. A daily protein intake of 1 to 1.5 g/kg of body weight is often an effective treatment modality for infants who have a mild form of the disorder. This can be supplied by diluting standard infant formula to decrease the protein content and adding a protein-free formula to meet nutrient needs. Specialized

formulas that limit threonine and isoleucine and omit methionine and valine are used, as clinically indicated, to support an adequate protein intake and growth.

Requirements for the limited amino acids may vary widely. Growth rate, state of health, residual enzyme activity, and overall protein and energy intakes must be monitored carefully and correlated with plasma amino acid levels. Adequate hydration is critical to maintain metabolic equilibrium. Food refusal and lack of appetite may complicate nutrition therapy, which compromises medical management.

## DISORDERS OF UREA CYCLE METABOLISM

All urea cycle defects result in an accumulation of ammonia in the blood. The clinical signs of elevated ammonia are vomiting and lethargy, which may progress to seizures, coma, and ultimately death. In infants the adverse effects of elevated ammonia levels are rapid and devastating. In older children symptoms of elevated ammonia may be preceded by hyperactivity and irritability. Neurologic damage may result from frequent and severe episodes of hyperammonemia. The severity and variation of the clinical courses of some urea cycle defects may be related to the degree of residual enzyme activity (Brusilow and Horwitz, 2010). The common urea cycle defects are discussed in a progression that proceeds around the urea cycle, as shown in Figure 44-5.

### Pathophysiology

**Ornithine transcarbamylase (OTC) deficiency** is an X-linked recessive disorder marked by blockage in the conversion of ornithine and carbamyl phosphate to citrulline. OTC deficiency is identified by hyperammonemia and increased urinary orotic acid, with normal levels of citrulline, argininosuccinic acid, and arginine. Severe OTC deficiency is

usually lethal in males. Heterozygous females with various degrees of enzyme activity may not demonstrate symptoms until they are induced by stress, as from an infection, or a significant increase in protein intake.

**Citrullinemia** is the result of a deficiency of argininosuccinic acid synthetase in the metabolism of citrulline to argininosuccinic acid. Citrullinemia is identified by markedly elevated citrulline levels in the urine and blood. Symptoms may be present in the neonatal period, or they may develop gradually in early infancy. Poor feeding and recurrent vomiting occur which, without immediate treatment, progress to seizures, neurologic abnormalities, and coma.

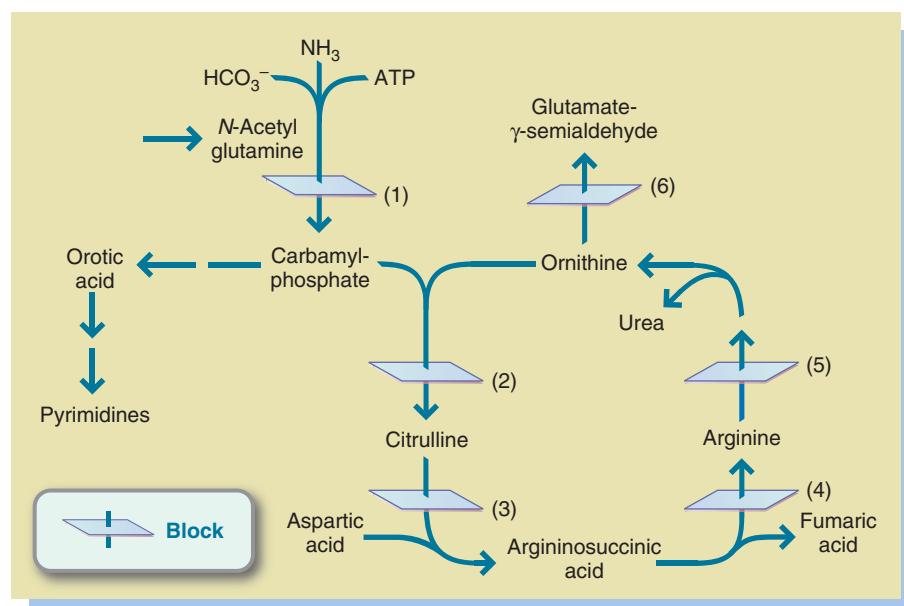

**Argininosuccinic aciduria (ASA)** results from deficiency of argininosuccinate lyase, which is involved in the metabolism of argininosuccinic acid to arginine. ASA is identified by the presence of argininosuccinic acid in urine and blood. L-Arginine must be supplemented to provide an alternative pathway for waste nitrogen excretion.

**Carbamyl-phosphate synthetase (CPS) deficiency** is the result of deficient activity of CPS. The onset is usually in the early neonatal period, with vomiting, irritability, marked hyperammonemia, respiratory distress, altered muscle tone, lethargy, and often coma. Specific laboratory findings usually include low plasma levels of citrulline and arginine and normal orotic acid levels in urine.

### Medical Treatment

Acute episodes of illness are managed by discontinuing protein intake and administering intravenous fluids and glucose to correct dehydration and provide energy. If hyperammonemia is severe, peritoneal dialysis, hemodialysis, or exchange transfusion may be required. Intravenous sodium benzoate or other alternative pathway compounds have been beneficial in reducing the hyperammonemia.

Neurologic outcome and intellectual development in individuals with urea cycle disorders vary, with a range from

**FIGURE 44-5** Urea cycle disorders.

1, Carbamyl-phosphate synthetase deficiency; 2, Ornithine carbamyl transferase deficiency; 3, Argininosuccinic acid synthetase (citrullinemia); 4, Argininosuccinic acid lyase (argininosuccinic aciduria); 5, Arginase deficiency (arginemia); 6, Adenosine triphosphate.

normal IQ and motor function to severe intellectual disability and cerebral palsy. Although information on long-term follow-up is limited, the use of alternative pathways for waste nitrogen excretion and a protein-restricted food pattern may improve the outcome.

## Medical Nutrition Therapy

Nutritional management of patients who have urea cycle disorders is a challenging task (Singh et al., 2005). The aim of therapy for the urea cycle disorders is to prevent or decrease hyperammonemia and the detrimental neurologic consequences associated with it. Treatment is similar for all of the disorders. For mildly affected infants a standard infant formula can be diluted to provide protein at 1 to 1.5 g/kg body weight per day. The energy, vitamin, and mineral concentrations can be brought up to recommended intake levels with the addition of a protein-free formula. However, for most individuals, specialized formulas are needed to adjust protein composition in an effort to limit ammonia production.

The amount of protein tolerated is affected by variables such as specific enzyme defect, age-related growth rate, health status, level of physical activity, amount of free amino acids administered, energy needs, residual enzyme function, and the use of nitrogen-scavenging medications. Recommendations must take family lifestyle and the individual's eating behaviors into consideration (Singh et al., 2005). Long-term therapy consists of restricting dietary protein to 1 to 2 g/kg/day, depending on individual tolerance. For most infants and children with these disorders, except for arginase deficiency, L-arginine supplements are required to prevent arginine deficiency and assist in waste nitrogen excretion. L-Arginine is supplemented based on individual needs, except in the case of arginase deficiency (Brusilow and Howich, 2010). Phenylbutyrate or other compounds that enhance alternative metabolic pathways are usually required to normalize ammonia levels.

## Protein-Restricted Diets

Infants and children with urea cycle defects or organic acidemias generally require restricted-protein intakes and specialized formulas. The amount of protein prescribed is based on the individual's tolerance or residual enzyme activity, age, and projected growth rate. The highest protein level tolerated should be given to ensure adequate growth and a margin of nutritional safety. The steps for effective planning of a low-protein food pattern are shown in Box 44-1.

In general, low-protein or restricted-protein food patterns can be formulated from readily available, lower-protein infant, toddler, and table foods. Special low-protein foods (see Table 44-5) can be used to provide energy, texture, and variety in the food pattern without appreciably increasing the protein load. The prescribed protein level can be met by adding a protein-free or specialized formula product to standard infant formula. Supplementing carbohydrate and fat makes up the resultant energy deficit.

## BOX 44-1

### Steps in Designing a Low-Protein Eating Plan

1. Determine the protein tolerance of the individual based on (1) diagnosis, (2) age, and (3) growth. Consider the metabolic stability and total protein intake required for the infant's or child's weight.
2. Calculate the protein and energy needs of the individual based on age, activity, and weight.
3. Provide at least 70% of total protein as high-biologic value protein from formula for infants and from milk or dairy foods for older children. Use a specialized formula if the infant or child cannot tolerate the entire protein intake from intact protein.
4. Provide energy and nutrient sources to meet basic needs.
5. Add water to meet fluid requirements and maintain appropriate concentration of formula mixture.
6. For the older infant and child, provide foods to meet food variety, texture, and energy needs.
7. Provide adequate intake of calcium, iron, zinc and all other vitamins and minerals for age.

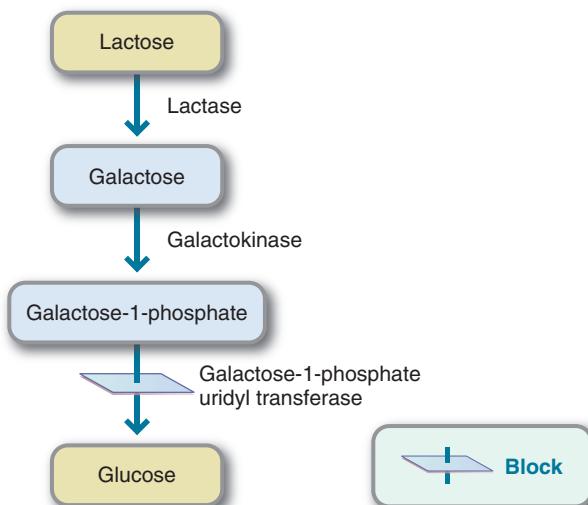

Specialty formulas are available when needed. The appropriate choice depends on the level of protein restriction, age, and condition of the child. The usual recommendations for energy density and vitamin and mineral composition are generally appropriate to support growth for the infant or child. Osmolarity of the formula must be considered; feedings of no more than 400 mOsm/L of solution have been recommended.

## DISORDERS OF CARBOHYDRATE METABOLISM

Disorders of carbohydrate metabolism vary in presentation, clinical course, and outcome. Galactosemia may present in the early newborn period as life-threatening seizures and sepsis. Hereditary fructose intolerance may present during midinfancy when solids that contain offending ingredients are introduced. Glycogen storage diseases (GSDs) may present at the time when feedings are spaced and subsequent hypoglycemia appears. All of these disorders require early and aggressive nutritional therapy.

### Galactosemia

**Galactosemia**, a high level of plasma galactose-1-phosphate combined with galactosuria, is found in two autosomal-recessive metabolic disorders: galactokinase deficiency and galactose-1-phosphate uridylyltransferase deficiency, which is also called "classic galactosemia." Illness generally occurs within the first 2 weeks of life. Symptoms are vomiting,

**FIGURE 44-6** Schematic diagram of the metabolism of galactose in galactosemia.

diarrhea, lethargy, failure to thrive, jaundice, hepatomegaly, and cataracts. Infants with galactosemia may be hypoglycemic and susceptible to infection from gram-negative organisms. If the condition is not treated, death frequently ensues secondarily to septicemia.

### Pathophysiology

Galactosemia results from a disturbance in the conversion of galactose to glucose because of the absence or inactivity of one of the enzymes shown in Figure 44-6. The enzyme deficiency causes an accumulation of galactose, or galactose and galactose-1-phosphate, in body tissues. In addition, expanded newborn screening programs have identified many newborns with Duarte galactosemia. These infants have one allele for galactosemia and one for “Duarte” galactosemia and are often said to have “DG/G galactosemia.” The Duarte allele produces approximately 5% to 20% of the GALT enzyme. Little is known about the natural history of DG galactosemia; apparently infants and children develop normally without medical complications.

### Medical Treatment

When diagnosis and therapy are delayed, intellectual disability can result (Waisbren, 2006). With early diagnosis and treatment, physical and motor development should proceed normally. However, intellectual achievement may be depressed. Patients often have IQs of 85 to 100; visual-perceptual and speech difficulties are common (Kaufman et al., 1995). Ovarian failure affects approximately 95% of women with galactosemia (Forges et al., 2006).

### Medical Nutrition Therapy

Galactosemia is treated by lifelong galactose restriction. Although galactose is required for the production of galactolipids and cerebrosides, it can be produced by an

alternative pathway if galactose is omitted from the diet. Galactose restriction mandates strict avoidance of all milk and milk products and lactose-containing foods because lactose is hydrolyzed into galactose and glucose. Effective galactose restriction requires careful reading of food product labels. Milk is added to many products, and lactose often appears in the coating of the tablet form of medications. Infants are fed soy-based formula. Some fruits and vegetables contain significant amounts of galactose. Whether these sources of galactose contribute to the pathophysiology characteristics of the disorder is unclear. Table 44-9 presents a low-galactose food pattern.

Medical opinions differ about the intensity and duration of treatment for Duarte galactosemia. Many centers eliminate galactose from the diets of these children for the first year of life; other centers do not.

### Glycogen Storage Diseases

**Glycogen storage diseases (GSDs)** reflect an inability to metabolize glycogen to glucose. There are a number of possible enzyme defects along the pathway. The most common of the GSD disorders are types I and III. Their symptoms are poor physical growth, hypoglycemia, hepatomegaly, and abnormal biochemical parameters, especially for cholesterol and triglycerides. Advances in the treatment of GSDs may improve the quality of life for affected children (Bali and Chen, 2010).

### Pathophysiology

GSD type Ia is a defect in the enzyme glucose-1-6-phosphatase, which impairs the formation of new glucose (**gluconeogenesis**) and the breakdown of glycogen from storage (**glycogenolysis**). The affected person is unable to metabolize glycogen stored in the liver. Severe hypoglycemia can result and cause irreparable damage.

Amylo-1, 6-glucosidase deficiency (GSD III or debrancher enzyme deficiency) prevents glycogen breakdown beyond branch points. This disorder is similar to GSD I in that glycogenolysis is inefficient but gluconeogenesis is amplified to help maintain glucose production. The symptoms of GSD III are usually less severe and range from hepatomegaly to severe hypoglycemia (Dagli et al., 2010).

### Medical Treatment

The outcome of treatment has been good. The hazard of severe hypoglycemic episodes is diminished, physical growth is improved, and liver size is decreased. The risk of progressive renal dysfunction is not entirely eliminated by current treatment, but liver transplantation for some types of GSD (e.g., type Ib) is sometimes an option. Treatment protocols for the GSDs are still evolving. The protocols include various kinds of carbohydrates at various doses during the day and night. Individual tolerance, body weight, state of health, ambient temperature, and physical activity all play important roles in designing the specific pattern of carbohydrate administration. The goal for all of the protocols remains the same: normalization of blood glucose levels.

**TABLE 44-9****Food Lists for Low-Galactose Food Pattern**

<b>Allowable Foods</b>	<b>Galactose-Containing Foods to Be Avoided*</b>
<b>Milk and Milk Substitutes</b>	
Similac Sensitive Isomil Soy Enfamil Prosobee Gerber Good Start Soy Plus	All forms of animal milk Imitation or filled milk Cream, butter, some margarines Cottage cheese, cream cheese Hard cheeses Yogurt Ice cream, ice milk, sherbet Breast milk
<b>Fruits</b>	
All fresh, frozen, canned, or dried fruits except those processed with unsafe ingredients <sup>†</sup>	
<b>Vegetables</b>	
All fresh, frozen, canned, or dried vegetables except those processed with unsafe ingredients, <sup>†</sup> seasoned with butter or margarine, breaded, or creamed	
<b>Meat, Poultry, Fish, Eggs, Nuts</b>	
Plain beef, lamb, veal, pork, ham, fish, turkey, chicken, game, fowl, Kosher frankfurters, eggs, nut butters, nuts	
<b>Breads and Cereals</b>	
Cooked and dry cereals, bread or crackers without milk or unsafe ingredients, <sup>†</sup> macaroni, spaghetti, noodles, rice, tortillas	
<b>Fats</b>	
All vegetable oils; all shortening, lard, margarines, and salad dressings except those made with unsafe ingredients <sup>†</sup> ; mayonnaise; olives	

\*Lactose is often used as a pharmaceutical bulking agent, filler, or excipient; thus tablets, tinctures, and vitamin and mineral mixtures should be evaluated carefully for galactose content. The *Physician's Desk Reference* now lists active and inactive ingredients in medications, as well as manufacturers' telephone numbers.

<sup>†</sup>Unsafe ingredients include milk, buttermilk, cream, lactose, galactose, casein, caseinate, whey, dry milk solids, or curds. Labels should be checked regularly and carefully because formulations of products change often.

**Medical Nutrition Therapy**

The rationale for intervention is to maintain plasma glucose in a normal range and prevent hypoglycemia by providing a constant supply of exogenous glucose. Administration of raw cornstarch at regular intervals and a high-complex carbohydrate, low-fat dietary pattern are advocated to prevent hypoglycemia. Some infants and children do very well with oral cornstarch administration, whereas others require glucose polymers administered via continuous-drip gastric feedings to prevent hypoglycemic episodes during the night (Bali and Chen, 2010; Dagli et al., 2010). The dose of cornstarch should be individualized; doses of 1.6 to 2.5 g/kg at 4- to 6-hour intervals are generally effective for young children with GSD I (Bali and Chen, 2010). The glucose vehicle suggested is a lactose-free formula. Iron supplementation is required to maintain adequate hematologic status because cornstarch interferes with iron absorption.

## **DISORDERS OF FATTY ACID OXIDATION**

Recent laboratory advancements have enabled identification of fatty acid oxidation disorders such as **medium-chain acyl-CoA dehydrogenase deficiency (MCAD)** and **long-chain 3-hydroxyacyl-CoA dehydrogenase deficiency (LCHAD)** (Figure 44-7). Children who are not identified by newborn screening usually present during periods of fasting or clinical illness with symptoms of variable severity, including failure to thrive, episodic vomiting, and hypotonia.

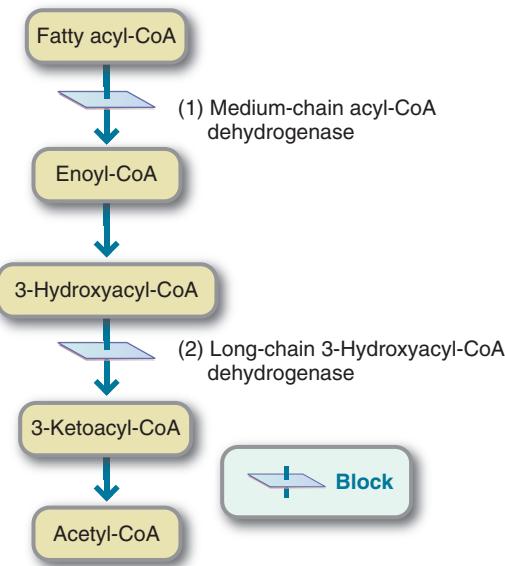

**Pathophysiology**

Children with MCAD who present clinically typically have hypoglycemia without urine ketones, lethargy, seizures, and coma. Children with LCHAD become hypoglycemic and demonstrate abnormal liver function, reduced or absent

ketones in the urine, and often secondary carnitine deficiency. They may also have hepatomegaly and acute liver disease. Hypoglycemia can progress quickly and be fatal (Matern and Rinaldo, 2005; Roe and Ding, 2010).

### Medical Nutrition Therapy

The concept underlying effective treatment for fatty acid oxidation disorders is straightforward: avoidance of fasting.

**FIGURE 44-7** Mitochondrial fatty acid oxidation disorders:  
1, Medium-chain acyl-Coenzyme A dehydrogenase deficiency, the most common fatty acid oxidation disorder.  
2, Long-chain 3-hydroxyacyl-CoA dehydrogenase deficiency.

This is accomplished by the regularly spaced intake of foods that provide an adequate energy intake and are high in carbohydrates. A low-fat diet is advocated because fats are not effectively metabolized. Consumption of not more than 30% of energy as fat has been recommended; some individuals require more restriction. Supplementation with L-carnitine, a substance that functions as a carrier of fatty acids across the mitochondrial membranes, is recommended by some centers. Children often do very well with three meals and three snacks offered at regular intervals. Most children may require additional carbohydrate, either a complex carbohydrate snack or uncooked cornstarch before bed, based on individual ability to maintain blood glucose levels throughout the night (Matern and Rinaldo, 2005). Depending on the disorder, supplementation with specific fatty acids (e.g., medium-chain fats for disorders that involve blocks of long-chain metabolism) may be indicated.

### ROLE OF THE NUTRITIONIST IN GENETIC METABOLIC DISORDERS

The role of the pediatric nutrition specialist in the treatment of metabolic disorders is a complex one that requires expertise in MNT for the specific disorder. Preparation and competency requires access to detailed information about the disorders and treatment modalities. A family-centered counseling approach, knowledge of feeding-skill development, and understanding of behavior modification techniques, as well as the support and counsel of a team of health care providers involved in the care of the patient, are also required. Nutrition intervention is often a lifelong consideration. Specific objectives of nutrition care are shown in Box 44-2.

#### BOX 44-2

##### Intervention Objectives for the Nutritionist Involved in the Treatment of Genetic Metabolic Disorders

In the clinic the registered dietitian (RD) has a major role in ongoing therapy and planning for each child. These responsibilities include gathering of objective food intake data from the family, assessing the adequacy of the child's intake, and working with the family to teach its members appropriate ways to monitor the restricted food intake pattern. The child with a metabolic disorder often presents with a wide range of concerns, which may include unstable biochemical levels, failure to gain weight, excessive weight gain, difficulty adhering to the diet, and behaviors that cause an adverse feeding situation. Thus managing a child with a metabolic disorder requires input from the entire health care team. The nutritionist uses skills and a basic knowledge of foods as sources of nutrients, parent-child relationships, growth, development, and interviewing to obtain the necessary information for assessing and planning for the child with a genetic metabolic disorder.

- I. The RD functions as an effective interdisciplinary team member by doing the following:
  - A. Becoming familiar with the background and current status of the child by reviewing the medical record
  - B. Recognizing and accepting the responsibility as the nutritionist by doing the following:
    1. Identifying appropriate intake of nutrients for growth, activity, and biochemical balance
    2. Identifying developmental stages of feeding behavior
    3. Understanding the concept of food as a support of developmental progress
    4. Identifying behavior as it affects nutrient intake
  - C. Understanding, respecting, and using the expertise of the team disciplines in providing care for the child

**BOX 44-2**

### Intervention Objectives for the Nutritionist Involved in the Treatment of Genetic Metabolic Disorders—cont'd

- II.** The RD provides adequate and supportive patient services by doing the following:
  - A.** Establishing a positive, cooperative working relationship with the parent and child
  - B.** Interviewing the parents about dietary intake and the feeding situation in a nonjudgmental manner
  - C.** Assessing the parent-child relationship as it relates to dietary management and control of the disorder
  - D.** Developing a plan for appropriate dietary management based on growth, biochemical levels, nutrient needs, developmental progress and nutrition diagnosis, such as:
    - Excessive protein intake
    - Altered nutrition-related laboratory values
    - Intake of inappropriate amino acids
    - Inadequate vitamin intake
    - Inadequate mineral intake
    - Food medication interaction
    - Food- and nutrition-related knowledge deficit
    - Limited adherence to nutrition-related recommendations
- E.** Developing a plan that includes appropriate foods and recognizes the parents' skills in food preparation, as well as family routines
- F.** Working with the parents to establish a method to deal effectively with negative feeding behaviors, if necessary
- G.** Contacting the family after receiving laboratory results and calculating food records to make necessary and appropriate changes in diet prescription
- H.** Supporting parents in their efforts at effective dietary and behavior management
- III.** The RD develops a professional database by doing the following:
  - A.** Becoming familiar with the current literature on the treatment of metabolic disorders
  - B.** Understanding the genetic basis of metabolic disorders
- IV.** The RD works with team members to understand the long-term patient care and create a written care plan for the patient.

### CLINICAL SCENARIO

The 1-day newborn screening test result for phenylalanine for a 7-lb, 4-oz male child was 3 mg/dL (180 mmol/L). The infant was breast-fed with no supplemental formula. A repeat sample was requested to further document the phenylalanine concentration in the infant's blood. The result from this sample, collected on day 5 of life, was 24 mg/dL (1440 mmol/L). To confirm the diagnosis for this child, which was considered to be "presumptive positive," a quantitative sample was obtained, and phenylalanine and tyrosine levels were measured. On day 9 of life the serum phenylalanine concentration was 25.5 mg/dL (1530 mmol/L), and the tyrosine level was 1.1 mg/dL (60.5 mmol/L); phenylalanine to tyrosine ratio was 23:2.

To provide adequate protein and energy intake and at the same time decrease the serum phenylalanine concentration, a phenylalanine-free formula was introduced at standard dilution without a phenylalanine supplement. Within 24 hours the infant's serum phenylalanine concentration had decreased to 16.5 mg/dL (990 mmol/L) while the infant was being provided an intake of 16 oz of formula. Within 48 hours the level was 8.8 mg/dL (528 mmol/L), with an intake of 18 oz of formula. At this point, standard infant formula was added to bring the calculated phenylalanine intake to approximately 60 mg/kg and to maintain a generous protein and energy intake for this 3.6-kg infant.

Phenylalanine concentrations were measured on alternate days for 4 days, and the levels were 7.6 mg/dL (456 mmol/L)

and 5.6 mg/dL (336 mmol/L), respectively. In subsequent weeks growth and serum phenylalanine concentrations continued to be monitored carefully, and energy and phenylalanine intakes were adjusted as necessary to maintain blood phenylalanine concentrations between 1 and 6 mg/dL (60–360 mmol/L) and to maintain growth in appropriate channels. The parents are apprehensive about preparing formula.

#### Nutrition Diagnostic Statement

Nutrition-related knowledge deficit related to the need for and preparation of a specialized formula (used for treatment of phenylketonuria in infants), as evidenced by a new diagnosis and the parents' asking for information

#### Nutrition Care Questions

1. What is the expected energy requirement for this infant with phenylketonuria?
2. What baseline formula would you use for this infant to provide phenylalanine at 60 mg/kg, formula at 20 kcal/oz, and protein and energy intakes at recommended levels?
3. What are the growth expectations for this infant?
4. What steps would you take if the plasma phenylalanine concentration exceeded 6 mg/dL (360 mmol/L) on subsequent measurements?

# Medical Nutrition Therapy for Intellectual and Developmental Disabilities

### KEY TERMS

Arnold Chiari malformation of the brain  
Asperger syndrome  
attention-deficit/hyperactivity disorder (ADHD)  
autism spectrum disorders (ASDs)  
cerebral palsy (CP)  
cleft lip and cleft palate (CL/CP)  
developmental disability  
Down syndrome (DS)  
fetal alcohol syndrome (FAS)  
hypotonia  
individualized education plan (IEP)

individualized family plan  
intellectual disability  
midfacial hypoplasia  
mosicism  
myelomeningocele (MM)  
nondysjunction  
oral-motor problems  
pervasive developmental disorder (PDD)  
Prader-Willi syndrome (PWS)  
spina bifida  
translocation

Individuals with developmental disabilities were generally housed in institutions for the first half of the 20th century. Little attention was paid to their education or medical or nutritional care. In 1963 the Developmental Disabilities Assistance and Bill of Rights Act was passed. Through this Act federal funds supported the development and operation of state councils, protection and advocacy systems, university centers, and projects of national significance. This Act provided the structure to assist people with developmental disabilities to pursue meaningful and productive lives. The institutions that housed these individuals were gradually closed or reduced in size. By 1975 these individuals were cared for at home, in schools, or in small residential facilities. In 1975 Public Law (P.L.) 94-142 was passed, opening public schools to children with developmental disabilities. In 1985 P.L. 99-487 (102-119 in 1992), the Early

Intervention Act, was passed, bringing services to children from birth to school age.

A **developmental disability** is defined as a severe chronic disability that is attributable to a mental or physical impairment or combination of mental and physical impairments. It is manifested before the person attains age 22; is likely to continue indefinitely; results in substantial functional limitations in three or more areas of major life activity (self-care, receptive and expressive language, learning, mobility, self-direction, capacity for independent living, and economic self-sufficiency); and reflects the person's need for a combination of generic or specialized interdisciplinary care, treatments, or other services that are lifelong or of extended duration and individually planned and coordinated. Developmental disabilities affect individuals of all ages and are not a disease state. They are conditions that are caused by fetal

abnormalities, birth defects, and metabolic and chromosomal disorders.

*Intellectual disability* replaced the term *mental retardation* in the 11th edition of the Definition Manual of the American Association on Intellectual and Developmental Disabilities (AAIDD, 2011). **Intellectual disability** is the most common developmental disability, characterized by significantly below-average intellectual functioning along with related limitations in areas such as communication, self-care, functional academics, home living, self-direction, health and safety, leisure, or work and social skills. It is estimated that 1% to 3% of the population have this diagnosis.

Developmental disabilities have been traced to many causes: chromosomal aberrations, congenital anomalies, specific syndromes, neuromuscular dysfunction, neurologic disorders, prematurity, cerebral palsy (CP), untreated inborn errors of metabolism, toxins in the environment, and nutrient deficiencies. The Centers for Disease Control and Prevention (CDC) reports that 3% of all live births have a birth defect (CDC, 2010) and there are 4.5 million Americans living with developmental disabilities (American Dietetic Association [ADA], 2010).

## MEDICAL NUTRITION THERAPY

Medical nutrition therapy (MNT) services vary depending on the individual's physical or mental problem, and much has been learned about the role of nutrition in both the prevention of disabilities and intervention when a nutrition problem exists. The role of the registered dietitian (RD) is essential. Because there is an abundance of information that parents and caretakers use from support groups and websites that are untested scientifically, RDs are often providing evidence-based counseling to counteract misinformation.

Numerous nutrition problems have been identified in the individual with developmental disabilities. Growth retardation, obesity, failure to thrive, feeding problems, metabolic disorders, medication-nutrient interactions, constipation, and renal problems may be present. Other health problems exist, depending on the disorder. Table 45-1 lists the most common developmental disabilities and their associated nutrition problems.

The ADA confirmed that nutrition services provided by RDs are essential components of comprehensive care for infants, children, and adults with intellectual and developmental disabilities. Nutrition services should be provided throughout the life cycle. Educational and vocational programs should provide MNT in a manner that is interdisciplinary, family centered, community based, and culturally competent (ADA, 2010).

### Nutrition Assessment

#### Anthropometric Measures

Anthropometric measures are altered when an individual is unable to stand, suffers from contractions, or has other gross motor problems. Measuring body weight may require

special equipment such as chair scales or bucket scales. Wheelchair scales are used in some clinics but require that the wheelchair weight be known. Obtaining height for the nonambulatory individual requires either a recumbent board that can be purchased or constructed. Other measures of height include arm span, knee-to-ankle height, or sitting height (Figure 45-1; see Appendixes 19 and 20).

Although growth charts for children with various syndromes do exist, most clinicians recommend using the general CDC charts (Appendices 9 to 16) because the information in the specialized charts is often based on small numbers, mixed populations, and old data (CDC, 2010). See Chapter 6.

Other measures that can be used to explore weight issues include arm circumference, triceps skinfold measures, and body mass index (BMI). BMI is a part of the CDC growth charts and can also be found in Appendixes 12, 16, and 23. Using the BMI for age can be controversial. For example, BMI is limited for identifying overweight in children who are overly fat because of decreased muscle mass and short stature.

#### Biochemical Measures

Laboratory assessment for the child and adult with developmental disabilities is generally the same as that discussed in Chapter 8 and Appendix 30. Additional tests may be indicated for the individual with epilepsy or seizures who is receiving an anticonvulsant medication such as phenytoin, divalproex sodium, topiramate, or carbamazepine. Use of these medications can lead to low blood levels of folic acid, carnitine, ascorbic acid, calcium, vitamin D, alkaline phosphatase, phosphorus, and pyridoxine. Assessment of thyroid status is part of the protocol for children with Down syndrome (DS), and a glucose tolerance test is recommended for evaluation of the child with Prader-Willi syndrome (PWS). As appropriate, genetic testing may be encouraged for both affected individuals and their biological family members.

#### Dietary Intake and Feeding Problems

Dietary information should be obtained for the child with a developmental disability through a diet history. However, there are difficulties in obtaining an accurate recall when the child is in a day-care center. Written diaries are also difficult to obtain when the child has multiple caretakers or when he or she is in school. When working with an adult with developmental disabilities, it is often difficult to obtain accurate information unless the individual has supervision, such as in special residential housing. Use of pictures and food models can often help in obtaining an estimate of the individual's intake.

Many children and adults with developmental disabilities display feeding problems that seriously decrease their ability to eat an adequate diet. Feeding problems are defined as the inability or refusal to eat certain foods because of neuromotor dysfunction, obstructive lesions such as strictures, and psychosocial factors (Cloud et al., 2005). Other causes of feeding problems in this population include oral-motor

**TABLE 45-1****Selected Syndromes and Developmental Disabilities: Frequent Nutrition Diagnoses**

<b>Syndrome or Disability</b>	<b>Underweight or Overweight/ Obesity</b>	<b>Altered Energy Requirements</b>	<b>Altered GI function</b>	<b>Feeding Problems</b>	<b>Other Issues</b>
<b>Cerebral Palsy</b>	A disorder of muscle control or coordination resulting from injury to the brain during its early (fetal, perinatal, and early childhood) development; there may be associated problems with intellectual, visual, or other functions.	Growth problems	Failure to thrive	Constipation	Oral/motor problems Central nervous system involvement; orthopedic problems; medication-nutrient interactions related to seizure disorder treatment
<b>Down Syndrome (Genetic Disorder)</b>	Results from an extra chromosome 21, causing developmental problems such as congenital heart disease, intellectual disability, small stature, and decreased muscle tone.	Risk for obesity	Related to short stature and limited activity	Poor suck in infancy	Gum disease; increased risk of heart disease; osteoporosis; Alzheimer's disease risk
<b>Prader-Willi Syndrome (Genetic Disorder)</b>	A disorder characterized by uncontrollable eating habits, inability to distinguish hunger from appetite; severe obesity; poorly developed genitalia; and moderate to severe intellectual disability.	Risk for obesity	Failure to thrive in infancy	N/A	Weak suck in infancy; abnormal food related activities
<b>Autism</b>	Classified as a type of pervasive developmental disorder; diagnostic criteria include communication problems, ritualistic behaviors, and inappropriate social interactions	N/A	N/A	Possible dysfunction	Limited food selections; strong food dislikes Pica; medication-nutrient interactions
<b>Spina Bifida (Myelomeningocele)</b>	Results from a midline defect of the skin, spinal column, and spinal cord; characterized by hydrocephalus, intellectual disability, and lack of muscular control.	Risk for obesity	Altered energy needs based on short stature and limited mobility	Constipation	Swallowing problems caused by Arnold Chiari malformation of the brain Urinary tract infections

difficulties, positioning problems, conflict in parent-child relationships, sensory issues, and tactile resistance from previous intubation (Tobin et al., 2005). The nutritional consequences of feeding problems include inadequate weight gain, poor growth in length, lowered immunity, anemia, vitamin and mineral deficiencies, dental caries, and psychosocial problems. Feeding problems should be assessed with an understanding of the normal development of feeding and the physical makeup of the mouth and pharynx (see Chapters 17–19 and Chapter 41).

Estimates are that feeding problems are found in 40% to 70% of children with special health care needs and 80% of children with developmental delays. Feeding problems are classified as oral motor, positioning, behavioral, and self-feeding. **Oral-motor problems** include difficulty with sucking, sucking, swallowing, and chewing. They also include sensory motor integration and problems with self-feeding and are described as exaggerations of normal neuromotor mechanisms that disrupt the rhythm and organization of oral-motor function and interfere with the feeding process (Box 45-1).

Children with developmental disabilities such as DS, CP, or cleft lip and palate often have oral-motor feeding

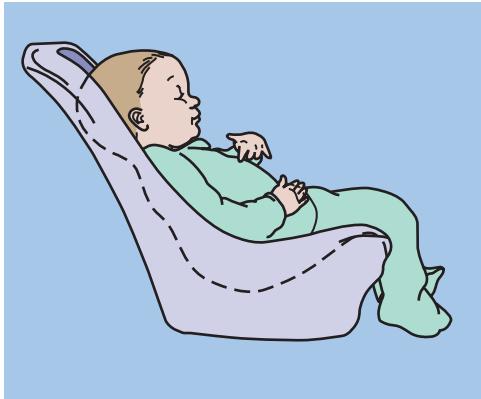

problems that may be related to the cleft, muscle tone, and inability to accept texture changes. The oral-motor problem can also be related to the developmental level, which may be delayed.

Positioning a child for feeding relates to his or her motor development, head control, trunk stability, and ability to have hips and legs at a right angle (Figures 45-2 and 45-3). This is frequently a problem for individuals with CP, spina bifida, and DS. However, without proper positioning, oral-motor problems are difficult to correct. The ability to self-feed may be delayed in the child with developmental disabilities and requires training by a feeding specialist. A feeding evaluation is best completed with actual observation by a team composed of a speech therapist, a dentist, a physical therapist, an occupational therapist, and an RD. An excellent interdisciplinary feeding evaluation form is the Developmental Feeding Tool shown in Figure 45-4. Frequently, adaptive feeding equipment is needed.

Behavioral issues may result from oral-motor or sensory problems, medical problems, certain medications, and the amount of emphasis placed on feeding. Issues such as control of the feeding process along with lack of autonomy in the

**BOX 45-1****Oral-Motor Problems**

<b>Problem</b>	<b>Description</b>
Tonic bite reflex	Strong jaw closure when teeth and gums are stimulated
Tongue thrust	Forceful and often repetitive protrusion of an often bunched or thick tongue in response to oral stimulation
Jaw thrust	Forceful opening of the jaw to the maximum extent during eating, drinking, attempting to speak, or general excitement
Tongue retraction	Pulling back the tongue within the oral cavity at the presentation of food, spoon, or cup
Lip retraction	Pulling back the lips in a very tight smile like pattern at the approach of the spoon or cup toward the face
Sensory defensiveness	A strong adverse reaction to sensory input (touch, sound, light)

**FIGURE 45-2** Proper feeding position for the infant. (From Cloud H: *Team approach to pediatric feeding problems*, Chicago, 1987, American Dietetic Association. © American Dietetic Association. Reprinted with permission.)

child may create negative behavior. Environmental factors also influence the eating behavior of the child. Examples include where the child is fed, distractibility, serving sizes, delayed weaning, and frequency of feeding.

### Nutrition Diagnosis

Once the nutrition assessment has been completed, problems should be identified related to growth. Excessive or inadequate weights; inadequate dietary intake; excessive or inadequate fluid intake; altered gastrointestinal problems such as constipation, vomiting, and diarrhea; intake of foods that are unsafe because of contamination or food allergies; food-medication interactions; chewing and swallowing

**FIGURE 45-3** Good feeding position for a child ages 6 to 24 months, showing hip flexion, trunk in midline, and head in midline. Good foot support with a stool should continue throughout childhood. (From Cloud H: *Team approach to pediatric feeding problems*, Chicago, 1987, American Dietetic Association. © American Dietetic Association. Reprinted with permission.)

difficulties; and problems with self-feeding may be issues. The nutrition diagnoses should be listed and priorities established. When possible, this information is shared with the parent, caregiver, or the adult client before the intervention process begins.

### Interventions

Once the nutrition diagnoses are identified and prioritized, short- and long-term goals should be set. Consideration must be given to the motivational level of the parent or client, his or her cultural background, and how the therapy can be community based and family centered. This means that consideration must be given to where the client will be served so that it becomes a part of the **individualized education plan (IEP)** or the **individualized family plan**.

Intervention plans should include all aspects of an individual's treatment program to avoid issuing an isolated set of instructions relevant to only one treatment goal. In some cases MNT may not be the family's first priority in the care of the child or adult, making it important for the RD to recognize the family's cues (see Chapter 15). Even when the family is ready for an intervention, such as weight management for a child with spina bifida, many factors require consideration. The parent or caregiver's educational level and income, language barriers, access to safe and

appropriate food, and family coping strategies should always be identified (see Chapter 15).

### Monitoring and Evaluation

Once MNT has been initiated, the need for follow-up evaluation and monitoring either by the RD or another health care professional is important. Giving information in writing, followed by a phone call, gives the chance to repeat some of the discussion and to answer any questions not asked during the initial session. Clarification of suggestions is often needed when monitoring nutrition changes that affect growth and development; a follow-up visit may also be needed.

A case manager may be involved who communicates with the adult with the disability. The RD may need to find appropriate resources to pay for supplemental nutrition products, tube feedings, and special food products as a part of the follow-up process. Community and agency resources will be discussed.

## CHROMOSOMAL ABERRATIONS

### Down Syndrome

**Down syndrome (DS)** is a chromosomal aberration of chromosome 21 (trisomy 21). It has an incidence of 1 in 700 live

births and results from the presence of an extra chromosome in each cell of the body. This anomaly causes the physical and developmental features of short stature; congenital heart disease; mental retardation; decreased muscle tone; hyperflexibility of joints; speckling of the iris (Brushfield spots); upward slant of the eyes; epicanthal folds; small oral cavity; short, broad hands with the single palmar crease; and a wide gap between the first and second toes (Capone et al., 2005).

### Pathophysiology

Normally every cell of the human body except for the gametes (sperm or ova) contains 46 chromosomes, which are arranged in pairs (see Chapter 5). With DS there is one extra chromosome for a total of 47. There are three processes by which this anomaly can occur: nondysjunction, translocation, and mosaicism. In **nondysjunction**, chromosome 21 fails to separate before conception and the abnormal gamete joins with a normal gamete at conception to form a fertilized egg with three of chromosome 21. This may also occur during the first cell division after conception. This type of DS is usually sporadic and has a recurrence rate of 0.5% to 1%. In **translocation**, the extra chromosome is attached to another chromosome (usually 14, 15, or 22). Approximately half the time, this type of DS is inherited from a parent who is a carrier; it has a much higher risk of recurrence in another pregnancy. In **mosaicism** the abnormal separation of chromosome 21 occurs sometime after conception. All future divisions of the affected cell result in cells with an extra chromosome. Therefore the child has some cells with the normal number of chromosomes and other cells with an extra chromosome. Frequently the child with this type of DS lacks some of the

more distinctive features of the syndrome (Capone et al., 2005) (see *Pathophysiology and Care Management Algorithm: Down Syndrome*).

### Medical Treatment

The National Down Syndrome Congress has published a listing of the health concerns for individuals with DS; many have nutrition implications (Table 45-2).

### Medical Nutrition Therapy

**Anthropometric Measures.** Height, weight, head circumference, triceps skinfold, and arm circumference are obtained for the child with DS with the usual measurements. See Chapter 6. BMI can be taken but may be higher than normal because of short stature. Growth measures are an important part of the assessment and ongoing nutrition therapy because these individuals tend to be short. Muscle tone is low and gross motor ability is often delayed, leading to the possibility of the individual becoming overweight. Monitoring should be frequent, and growth plotted on the CDC charts (see Appendixes 9 through 16).

**Biochemical Measures.** Numerous studies have shown biochemical and metabolic abnormalities in individuals with DS; however, many have involved small samples and were difficult to interpret (Capone et al., 2005). Although serum concentrations of albumin have been found to be low, the guidelines from the Down Syndrome Medical Congress do not list serum albumin assessment as routine. Increased glucose levels have been reported, with an increased incidence of diabetes mellitus.

Current guidelines for the treatment of infants and children with DS include evaluation of thyroid function at birth and thereafter annually.

**TABLE 45-2**

**Health Concerns of Children with Down Syndrome**

Health Concern	Implications	Treatment
Congenital heart disease	40%-50% of population	Medication or surgical repair
Hypotonia	Reduced muscle tone, increased range of joints	
Motor function problem	Poor physical function	Early intervention for physical therapy, occupational therapy
Delayed growth	Short stature	In some cases growth hormone
Developmental delays	Poor physical, emotional function	Early intervention
Hearing concerns	Small ear canals, otitis media, conductive impairment	Early intervention
Dental problems	Decreased saliva, reflux, and vomiting	Low sucrose intake
Ocular problems	Refractive errors, strabismus, cataracts	Corrective glasses
Cervical spine abnormality		None
Thyroid disease	Hypothyroidism	Thyroid supplement, tests repeated annually
Overweight	Excessive weight gain, inactivity	Decrease energy, increase activity
Seizure disorders	Variable nutrient intake	Medications
Emotional disorders	May occur late in childhood	Medication, counseling

Updated from Saenz RB: Primary care of infants and young children with Down syndrome, Am Fam Phys 59:381, 1999.

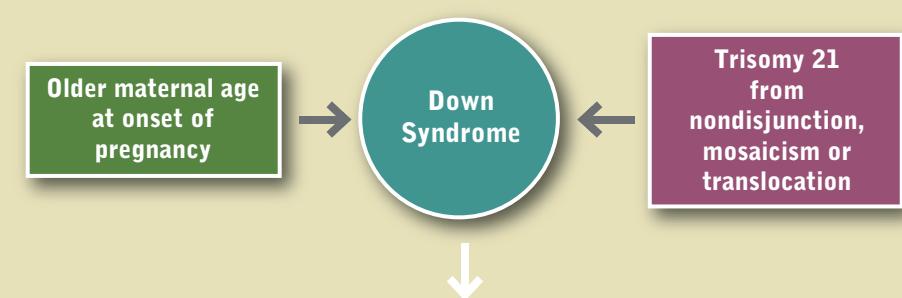

## PATHOPHYSIOLOGY AND CARE MANAGEMENT ALGORITHM

### Down Syndrome

**Etiology**

**Pathophysiology**

**Management**

#### Clinical Findings

- Hypotonia
- Hyperflexibility/mobility of the joints
- Hip subluxation or dislocation
- Scoliosis
- Foot deformity
- Microbrachycephaly
- Short neck
- Depressed nasal bridge and small nose
- Upward slanting eyes
- Abnormally shaped ear
- Enlarged, protruding tongue
- Single simian crease in center of the palm
- Excessive space between large and second toe
- Mental retardation
- Speech and motor delay
- Cardiac anomalies
- GI atresia or stenosis
- Hearing loss
- Hypothyroidism
- Dental problems

#### Nutrition Assessment

- Feeding problems
- Nutritional intake
- Fluid intake
- BMI compared with Down syndrome standards
- Weight changes
- Dysphagia

#### Medical Management

- Monitor for leukemia
- Management of infections
- Management of respiratory problems
- Signs of Alzheimer's disease later
- Annual monitoring of hypothyroidism

#### Nutrition Care

- Feeding management
- Feeding environment
- Use of adaptive feeding utensils
- Monitor weight changes
- Monitor for signs of nutrient deficiencies

**Dietary Intake.** During infancy the food intake of the infant with DS may differ from that of the normal infant. Although human breast milk is recommended, many infants with DS are formula fed. Infant illnesses, admission to the neonatal unit, frustration, depression, perceived milk

insufficiency, and difficulty in suckling by the infant are reasons why formula feeding is used.

Progression to solid food has been found to be delayed in children with DS, mostly as a result of delays in feeding and motor development. Introduction of solid food may not be

**TABLE 45-3****Estimated Caloric Needs for Special Conditions**

<b>Condition</b>	<b>kcal/cm</b>	<b>Comments</b>
Normal child	Average 16	
Prader-Willi	Maintain growth: 10-11 Promote weight loss: 8.5	For all children and adolescents
Cerebral palsy		
Mild	14	Reliable for ages 5-11 yr
Severe, limited mobility	11	Reliable for ages 5-11 yr
Down syndrome	Girls: 14.3 Boys: 16.1	Reliable for ages 5-11 yr
Motor dysfunction		
Nonambulatory	7-11	Reliable for ages 5-12 yr
Ambulatory	14	Reliable for ages 5-12 yr
Spina bifida	Maintain weight: 9-11 Promote weight loss: 7	For all children older than 8 years of age and minimally active

Modified from Rokusek C, Heindicles E: Nutrition and feeding for persons with special needs, with permission of the South Dakota University Affiliated Program, Interdisciplinary Center for Disabilities, 1992.

offered at 6 months if the infant has poor head control or is not yet sitting. Low tone and sucking problems also delay weaning from the breast or bottle to the cup. IEPs include feeding and feeding progression instruction and practice.

An important part of evaluating the dietary intake is determining energy and fluid needs, because children with DS have a high prevalence of obesity. Studies have indicated that the resting energy expenditure (REE) of the child with DS is lower than for controls without DS—and may be as much as 10% lower than the dietary reference intake (DRI) for energy. For the child older than the age of 5, calculations for energy requirements may need to be based on height rather than weight (Table 45-3) (see Chapter 2).

**Feeding Skills.** Feeding skills are delayed in the infant and child with DS. Some parents find difficulty in initiating oral motor skills such as suckling and sucking. The infant with DS often has difficulty in coordinating sucking, swallowing, and breathing, which are the foundations for early feeding. When the infant has a congenital heart defect, which occurs in 40% to 60% of the DS infants, sucking is weakened, and fatigue interferes with the feeding process. Gastrointestinal anomalies are found in 8% to 12% of infants with DS, and these infants often require nasogastric or gastrostomy feedings.

Other physical factors that make feeding difficult in the first years of life include a **midfacial hypoplasia** (a craniofacial deformity common in cleft palate), a small oral cavity, a small mandible, delayed or abnormal dentition, malocclusion, nasal congestion, small hands, and short fingers. Weaning and self-feeding are usually late when compared with the normal infant, and frequently do not emerge until 15 to 18 months of age. The DS infant strives for independence and autonomy approximately 6 months later than the child without DS.

**Intervention Strategies**

**Overweight.** The most effective intervention for the overweight child with DS is to design a calorie-controlled eating plan based on kilocalories per centimeter of height (see Table 45-3). Dietary management includes assessing the feeding developmental level of the child, working with a physical therapist related to gross motor skills to determine possible activity levels, and making environmental changes. Environmental changes should include following a regular eating schedule that includes three meals at regular times with the child sitting either in a high chair or at the table. Planned snacks should be low in fat and sugar. Soft drinks should be eliminated, and milk should be low fat (after age 2). Physical activity should be encouraged. Counseling in which the parent helps determine a realistic plan should focus on serving sizes and food preparation and decreasing the number of times meals are purchased in fast-food restaurants. If the child or adolescent is school age, a prescription for a special meal at school can be obtained by using the school food service prescription (to be discussed later in the chapter).

**Feeding Skills.** Often parents wrongly expect different feeding development for the child with DS. Behavioral problems related to feeding usually develop based on what happens between the parent and child at mealtime. An example of this is the unnecessary delay of weaning to a cup or progression of food textures because of inadequate effort or education. During intervention programs the feeding team can guide the parent in positioning the child and working toward attainable feeding skills related to the developmental level of the child.

**Constipation.** This is a frequent problem for the child with DS because of overall low tone followed by lack of fiber and fluid in the diet. Treatment should involve increasing

fiber and fluid, with water consumption emphasized. Fiber content of the diet for children after age 3, is 5 to 6 g per year of age per day. For adults the recommendation is for 25 to 30 g of dietary fiber daily.

## Prader-Willi Syndrome

**Prader-Willi syndrome (PWS)** was first described in 1956 by Doctors Prader, Willi, and Lambert. It is a genetic condition caused by the absence of chromosomal material. PWS occurs with a frequency of 1 in 10,000 to 1 in 25,000 live births. Characteristics of the syndrome include developmental delays, poor muscle tone, short stature, small hands and feet, incomplete sexual development, and unique facial features. Insatiable appetite leading to obesity is the classic feature of PWS; however, in infancy the problem of **hypotonia** (low muscle tone) interferes with feeding and leads to failure to thrive (McCune and Driscoll, 2005). Developmental delays (affecting 50% of the population), learning disabilities, and mental retardation (affecting 10%) are associated with PWS.

The genetic basis of PWS is complex. Individuals with PWS have a portion of genetic material deleted from chromosome 15 received from the father. Of the cases of PWS, 70% are caused from the paternal deletion, occurring in a specific region on the q arm of the chromosome. PWS can also develop if a child receives both chromosome 15s from the mother. This is seen in approximately 25% of the cases of PWS and is called *maternal uniparental disomy*. Early detection of PWS is now possible because of the use of deoxyribonucleic acid methylation analysis, which correctly diagnoses 99% of the cases (McCune and Driscoll, 2005). This is an important development in the early identification and subsequent treatment of these children to prevent obesity and growth retardation and is used to identify the infant born with features and characteristics described previously.

## Pathophysiology

**Metabolic Abnormalities.** Short stature in the individual with PWS has been attributed to growth hormone deficiency. In addition to decreased growth hormone release, children have low serum insulin-like growth factor (IGF)-1, low IGF-binding protein-1, and low insulin compared with normal obese children. Growth hormone therapy was approved by the Food and Drug Administration in 2000, and in one 5-year study in Japan 37 patients from age 3 to 21 years experienced significant increase in height gain velocity when given growth hormone (Obata et al., 2003). A more recent study (Carrel et al., 2010) found that GH therapy of infants and toddlers for 12 months significantly improved body composition and mobility skill acquisition.

In addition to the growth hormone deficiency, individuals have a deficiency in the hypothalamic-pituitary-gonadal axis, causing delayed and incomplete sexual development. Finally there is a decreased insulin response to a glucose load in children with PWS compared with age-matched non-PWS obese children (Talebizadeh and Butler, 2005).

**Appetite and Obesity.** Appetite control and obesity are common problems for individuals with PWS. After the

initial period of failure to thrive, children begin to gain excessively between the ages of 1 and 4, and appetite slowly becomes excessive. Based on longitudinal study, Miller et al describe this gradual and complex progression in terms of 7 nutritional phases based on levels of appetite, metabolic changes and growth. In fact, some adults with PWS may progress to the last stage - one, with no insatiable appetite and the person is able to feel full (Miller et al, 2011).

This uncontrollable appetite, a classic feature of PWS, when combined with overeating, a low basal metabolic rate, and decreased activity, leads to the characteristic obesity. The cause of the uncontrollable appetite is suspected to involve the hypothalamus and altered levels of satiety hormones and peptides such as ghrelin (Scerif et al, 2011).

Body composition is an important consideration in the evaluation of individuals with PWS. They have decreased lean body mass and increased body fat, even in infancy (Reus et al, 2011). Body fat is generally deposited in the thighs, buttocks, and abdominal area. The lowered energy expenditure is found in young children, adolescents, and adults with PWS, with one study showing adolescents with PWS having a total energy expenditure (TEE) 53% of that of normal obese adolescents (McCune and Driscoll, 2005). The low muscle tone contributes greatly to the lack of interest in physical activity.

## Nutrition Assessment

**Anthropometric Measures.** Height measurements tend to be lower in PWS infants and young children, with the rate of height gain tapering off between the ages of 1 and 4. The usual measurements of length or height, weight, and head circumference should be taken and plotted on the CDC growth curves. Other measures of interest include arm circumference and triceps skinfold measures. BMI may be distorted for the individual with PWS because of the short stature; however, plotting the BMI over time is useful in determining unusual changes (see Appendixes 12 and 16). It is important that anthropometric measures be taken frequently and reported to the parents or caregiver.

**Biochemical Measures.** Biochemical studies are generally the same for the PWS individual, with the exception of either fasting blood glucose tests or glucose tolerance tests. These are added because of the risk for diabetes mellitus, possibly related to the decreased insulin response and obesity that usually accompanies PWS.

**Dietary Intake.** Dietary information varies for individuals with PWS, depending on their age. In infancy the dietary information should be obtained with a careful dietary history and analyzed for energy and nutrient intake. Infants are commonly difficult to feed because of their hypotonia, poor suck, and delayed motor skills. Generally their feeding development is slower than in the normal infant, and transitioning to food at 4 to 6 months of age may be difficult. Many of these infants have gastroesophageal reflux requiring medication or thickening of their formula.

During the toddler years weight gain may increase rapidly as dietary intake increases. This requires careful assessment of portion sizes, frequency of feeding, and types of foods

served. Although some parents may report that the child with PWS does not eat more than other children in the family, they need to be educated that the energy needs of the child are lower because of the reduced lean muscle mass and slow development of motor skills and activity. As the child gets older, interest in food increases; and, starting around ages 5 through 12, the child may be hungry all the time and display difficult behaviors such as tantrums, stubbornness, and food stealing. Many parents have found it necessary to lock cabinets, refrigerators, and the kitchen door to control food intake. Information gathered during the dietary interview should include asking about environmental control techniques.

Determination of energy needs for the infant with PWS is the same as for a normal infant. However, as the child enters the toddler years, he or she will need fewer calories to maintain weight gain along the growth curve. This will apply in adulthood when fewer calories are needed to maintain weight. Energy needs have been calculated according to centimeters of height from 2 years on. It has been recommended that the macronutrient intake of the diet be 25% protein, 50% carbohydrate, and 25% fat (see Table 45-3).

**Feeding Skills.** The infant with PWS often presents with weak oral skills and poor sucking skills in the first year of life. As the child matures, feeding skills are not a problem, but they may be delayed. Chewing and swallowing problems are not usually seen, although they may be associated with the low muscle tone. Behavioral feeding issues are associated with an insatiable appetite and not being provided with food. This can bring about tantrums.

### Intervention Strategies

Intervention for PWS should occur at each developmental stage: infancy, toddler, preschool age, school age, and adult.

**Infancy.** Providing adequate nutrition as established by the American Academy of Pediatrics (AAP) related to breastfeeding or formula feeding is recommended. Because feeding may be difficult related to sucking, concentrating the formula or breast milk may be necessary to promote adequate weight gain. Feeding intervention will assist in improving the sucking problems caused by hypotonia. As the infant matures, a concentrated formula is not necessary, and foods can be added when head control and trunk stability are achieved, usually at approximately ages 4 to 6 months.

**Toddler and Preschool Age.** Most children begin to gain excessive weight between 1 and 4 years of age. Beginning a structured dietary protocol for the child and the family is important so that the toddler learns that meals are provided at specified times so that a pattern of grazing doesn't develop. Parents should be taught to provide small servings of meats, vegetables, grains, and fruits and limited amounts of sweets. Early intervention for these children in the preschool years is very important in working with feeding issues and intake control as they grow older. Weight, height, and nutrient intake should be monitored monthly, and energy needs adjusted if weight gain becomes excessive. Concurrently physical activity must be encouraged as a part

of the IEP, and physical therapy services made available if necessary.

**School Age.** For the school-age child, collaboration with the school food service program becomes important. Energy needs should be calculated per centimeter of height (see Table 45-3) and are generally 50% to 75% of the energy needs of unaffected children. This may require using the prescription for special meals through the school food service program. At home environmental controls may be required, with cupboards and refrigerators being locked, because the child and adolescent have limited satiety, and will search for food away from mealtime. Some parents say that growth hormone therapy for their child helps, but it doesn't seem to change the child's lack of satiety. Appetite-suppressing medications have been used but are largely unsuccessful.

**Adulthood.** Prevention of obesity is truly the key for successful treatment of PWS; however, many adults who are not identified early become very obese. Weight management programs providing a very low 6 to 8 kcal per centimeter of height may be required. Nutrient values should be calculated, and vitamin-mineral supplements added, as well as essential fatty acids (EFAs) if indicated. Many dietary treatments have been tried such as the ketogenic diet and the protein-sparing modified-fast diets. However, with any approach strict supervision is usually required, and great emphasis must be placed on physical activity. A behavior management approach has also been recommended to implement both the dietary management and physical activity plans. In many states there are group homes for adults with PWS where supervised independent living is possible and meals can be very structured and exercise programs implemented.

MNT of children and adults with PWS requires follow-up with many health care providers and schools. Fortunately parents of the individual with PWS now have access to a number of support groups and organizations dedicated to education, research, and establishing treatment programs.

## NEUROLOGIC DISORDERS

### Spina Bifida

**Spina bifida** is a neurologic tube defect that presents in a number of ways: meningocele, **myelomeningocele (MM)**, and spina bifida occulta. MM is the most common derangement in the formation of the spinal cord and generally occurs between 26 to 30 days of gestation, with the date of occurrence affecting the location of the lesion. The lesion may occur in the thoracic, lumbar, or sacral area and will influence the amount of paralysis. The higher the lesion, the greater is the paralysis. Manifestations range from weakness in the lower extremities to complete paralysis and loss of sensation. Other manifestations include incontinence and hydrocephalus. The incidence of spina bifida is about 1 in 1430 births in the United States (CDC, 2010).

Prevention of spina bifida is now possible. In the 1980s, studies reported a positive effect from supplementation of

mothers with folic acid plus multivitamins (Smithells et al, 1983). This reduced the risk of a second pregnancy with spina bifida as an outcome. As a result of numerous studies showing folic acid supplementation before conception to be effective, the national recommendation is 400 mcg/day for all women of childbearing age. Folic acid has been added to many flours and other cereal and grain products in the food supply since 1996 (CDC, 2010). These public health measures have resulted in increased folic acid blood levels in U.S. women of childbearing age and a decrease of 20% in the national rate of spina bifida (Robbins et al., 2006) (see Chapter 16).

## Pathophysiology

The spinal lesion may be open and can be surgically repaired shortly after birth, usually within 24 hours to prevent infection. Although the spinal opening can be surgically repaired, the nerve damage is permanent, resulting in the varying degrees of paralysis of the lower limbs. In addition to physical and mobility issues, most individuals have some form of learning disability.

The spinal lesion affects many systems of the body and can result in weakness in the lower extremities, paralysis, and nonambulation; poor skin condition caused by pressure sores; loss of sensation and bladder incontinence; hydrocephalus; urinary tract infections; constipation; and obesity. Seizures also occur in approximately 20% of children with MM and require medication. Chronic medication is required for prevention and treatment of urinary tract infections and for bladder control. The resultant nutrition problems include obesity, feeding problems, constipation, and drug-nutrient interaction problems. Children with spina bifida may be allergic to latex. It has been recommended that they avoid certain foods such as bananas, kiwi, and avocados. Mild reactions can occur from apples, carrots, celery, tomatoes, papaya, and melons (Cloud et al., 2005) (see Box 27-3 in Chapter 27).

## Nutrition Assessment

**Anthropometric Measures.** Infants and children with neural tube defects are usually shorter because of reduced length and atrophy of the lower extremities, although other problems such as hydrocephalus, scoliosis, renal disease, and malnutrition may contribute. The level of the lesions can also affect the length and height of the individual.

Obtaining accurate length and height measures can be difficult, especially as the child grows older. An alternate measure for determining height, the arm span/height ratio, is used and modified, depending on leg muscle mass. Arm span can be used directly as a height measure (arm span  $\times$  1) if there is no leg muscle mass loss, as in a sacral lesion. Arm span  $\times$  0.95 can be used to determine height if there is partial leg muscle loss, and arm span  $\times$  0.90 is used for a height measurement when there is complete leg muscle loss such as with a thoracic spinal lesion (Ekvall and Cerniglia, 2005). See Fig. 45-1 and Appendix 20.

Weight measures can be obtained for the child unable to stand by using chair scales, bucket scales, and wheelchair

scales. To monitor the weight accurately, it should be obtained in a consistent manner, with the person in light clothing or undressed. Triceps skinfold measures can also be used, along with subscapular measures and abdominal and thorax measures, to determine the amount of body fat. See Chapter 6.

Head circumference should be measured in infants and toddlers up to age 3. A high percentage of children with spina bifida have head shunts as a result of their hydrocephalus. Unusual changes in the size of the head may indicate a problem with the shunt.

**Biochemical Measures.** Most protocols in the treatment of spina bifida include iron status tests, measurements of vitamin C and zinc levels, and other tests related to the nutritional consequences of medications needed for seizures and urinary tract infection control (see Chapter 9 and Appendix 31).

**Dietary Intake.** Many children with spina bifida eat a limited variety of foods, and they are frequently described as a “picky eaters” by the parents. When doing a dietary history, it is important to ask about the variety of foods, particularly of high-fiber foods. The school-age child may be prone to skipping breakfast because early morning preparations for school require more time than for the non-affected child.

Energy needs are lower for the child with spina bifida (see Table 45-3), and calorie requirements must be determined carefully to prevent the obesity to which many are prone. Ekvall and Cerniglia (2005) found that for MM children 8 years or older, the caloric need is 7 cal/cm of height for weight loss and 9 to 11 cal/cm of height to maintain weight. It is important to evaluate how the mother or caretaker perceives food for the child since it represents sympathy and love for many parents.

It is important to evaluate fluid intake because so many children have urinary tract infections and may be drinking inadequate amounts of water and excessive amounts of soft drinks or tea. Cranberry juice can be offered. Physical activity must also be evaluated and may be found to be very limited, particularly when the child is nonambulatory. Ambulatory individuals with a shunt may be restricted from contact sports but can be involved in walking and running.

Feeding skills need to be evaluated, along with oral motor function in particular. Many children with spina bifida are born with **Arnold Chiari malformation of the brain**, which affects the brainstem and swallowing. See Appendix 35 for dietary recommendations for dysphagia. Difficulty in swallowing may contribute to the child avoiding certain foods later in life. Because of this there may be delays in weaning from the breast or bottle to the cup, but there should be no delays in gaining self-feeding skills.

**Clinical Evaluation.** Evaluation should include looking for pressure sores and signs of dehydration, along with asking about the amount and type of fluids consumed. Constipation may be caused by the neurogenic bowel combined with a diet low in fiber and fluids. The evaluation should include a review of food intake, fiber content, and fluids.

## Intervention Strategies

Many children with spina bifida are overweight. It usually occurs when ambulation is a problem leading to decreased energy needs. Refusal to accept a wide variety of foods is common. Frequent feeding is both an oral-motor and a behavioral problem. Counseling should include introducing foods around age 6 months, limiting the intake of high-sucrose infant jar foods, and training the child to accept a wide variety of flavors and textures.

Obesity prevention should include addressing the problems of limited physical activity, increasing fluids and fiber and calculating the appropriate amount of calories. Once the child is in school, the food service manager should be provided with a prescription for a low-calorie breakfast and lunch, and weight management program should be listed as a part of the IEP. Enrollment in a group weight management program has been used successfully with modification of the accompanying physical exercise. The ideal program uses a team approach with involvement of the RD, nurse, occupational therapist, physical therapist, educator, and psychologist.

In many clinics the child or adult with spina bifida is seen on a semiannual or annual basis. This frequent follow-up is necessary and should include monitoring of growth, particularly weight; food and fluid intake; and medication use. School programs and IEPs are excellent follow-up tools; however, the school often lacks appropriate scales for weighing a nonambulatory student. In this situation the parent should be encouraged to bring the child to the clinic for weight checks or, if distance is a problem, find a long-term care facility that will permit use of its scales. Follow-up by phone contact or e-mail can be done for evaluating dietary intake and fluid management.

## Cerebral Palsy

**Cerebral palsy (CP)** is a disorder of motor control or coordination resulting from injury to the brain during its early development. Among the causative agents of CP are prematurity; blood-type incompatibility; placental insufficiency; maternal infection that includes German measles; other viral diseases; neonatal jaundice; anoxia at birth; and other bacterial infections of the mother, fetus, or infant that affect the central nervous system.

The problem in CP lies in the inability of the brain to control the muscles, even though the muscles themselves and the nerves connecting them to the spinal cord are normal. The extent and location of the brain injury determine the type and distribution of CP. The incidence of CP varies with different studies, but the most commonly used rate is 2 to 3 in 1000 live births. The prevalence of premature births has contributed to maintenance of this figure despite electro-fetal monitoring.

## Pathophysiology

There are various types of CP, which are classified according to the neurologic signs involving muscle tone and abnormal motor patterns and postures. The diagnosis of CP is

## BOX 45-2

### Different Types of Cerebral Palsy

**Spastic CP:** Increased muscle tone, persistent infant reflexes, increased deep tendon reflexes in one of three patterns: hemiplegia (arm and leg on one side of the body), diplegia (involving the lower extremities), and quadriplegia (all four extremities and may include the trunk, head, and neck)

**Dyskinetic CP:** Abnormalities in muscle tone that affect the entire body; includes athetoid CP, which includes uncontrolled and continuous involuntary movements

**Mixed CP:** A condition in which both athetosis and spasticity are present

**Ataxic CP:** Abnormalities of voluntary movement and balance such as unsteady gait

**Athetoid dyskinetic CP:** Normal intelligence but difficulty walking, sitting, speaking clearly

Data from 4MYCHILD: What type of cerebral palsy does my child have? Accessed 8 November 2010 from <http://www.cerebralpalsy.org/types-of-cerebral-palsy/>.

CP, Cerebral palsy.

generally made between 9 to 12 months of age and as late as 2 years with some types (Box 45-2).

Poor nutrition status and growth failure, often related to feeding problems, are common in children with CP. Meeting energy and nutrient needs is particularly difficult in children and adults with more severe forms of CP such as spastic quadriplegia and athetoid CP. For example, bone mineral density of children and adolescents with moderate to severe CP is reduced in those with gross motor function and feeding difficulties (Henderson et al., 2005).

Other health problems include constipation, usually caused by inactivity and lack of fiber and fluids, often connected to feeding problems. Dental problems occur and are often related to malocclusion, dental irregularities, and fractured teeth. Lengthy and prolonged bottle-feedings of milk and juice promote the decay of the primary upper front teeth and molars (see Chapter 26). Hearing problems and especially visual impairments, mental retardation, respiratory problems, and seizures affect nutrition status. Seizures are controlled with anticonvulsants, and a number of drug-nutrient interaction problems occur (see Chapter 9 and Appendix 31).

## Nutrition Assessment

**Anthropometric Measures.** This is an important area of assessment because of the growth failure of the more severely involved child or adult with CP. Children with CP are often shorter, and, depending on the level of severity, some children with CP may need to be measured for length using recumbent length boards or standing boards even as they grow older. See Appendix 20. However, some of the measuring devices are inappropriate for the child with contractures and inability to be stretched out full length.

Arm span can be used when the individual's arms are stretchable, as well as upper arm and lower leg length. Stevenson (2005) has recommended lower leg length or knee height as a possible measure for determining height for both children and adults with lower-leg CP (Fig. 45-1). The CDC recommends using the CDC curves designed for nonaffected children, plotting sequentially for indications of malnutrition rather than using the disease-specific curves.

Weight measures should be collected over time. Scales may require modifications, with positioning devices for the individual with CP who has developed scoliosis, contractures, and spasticity. Working with a physical therapist to find a positioning device that can be placed in a chair scale or using a bucket scale often works well. Mid-upper arm circumference and triceps skinfold measures are recommended reliable ways to screen for fat stores in children with CP. Head circumference should be measured regularly from birth to 36 months and plotted on the CDC growth curves.

**Biochemical Measures.** Although there are no specific laboratory tests indicated for the child with CP, a complete blood count, including hemoglobin and hematocrit, should be done when food intake is limited and malnutrition is a possibility. Because bone fractures are a significant problem for many children and adults with spastic quadriplegia, bone mineral density may need evaluating. Medications for seizures may be given; many have nutrition interaction problems (see Appendix 31). Evaluation of vitamin D, calcium, carnitine, and vitamin K levels is recommended.

**Dietary Intake.** Feeding methods can result in limiting the intake of food and fluid; caretakers may not provide sufficient food to meet nutritional needs. The energy needs of the individual with CP vary according to the type of CP. Studies show that the REE and TEE are lower in those with spastic quadriplegic CP than in normal controls (see Table 45-3).

### Intervention Strategies

A high percentage of children with CP have feeding problems that are largely the result of oral-motor, positioning, and behavioral factors. As infants they have difficulty swallowing and coordinating swallowing and chewing, so that the normal progression to solid foods is later than usual. All this may lead to inadequate intake and growth limitations. For those infants and children with IEPs, the team of dietitian, speech therapist, occupational therapist, and physical therapist should evaluate the problem and work together in planning therapy.

Gastroesophageal reflux is frequently seen in these infants and toddlers. A tube feeding may be required if a modified barium swallow reveals aspiration. Alternative techniques in feeding should be considered, which could include thickening all beverages or placing a gastrostomy tube (Sullivan, 2005). RDs should evaluate gastrostomy feedings for caloric and nutritional value, volume required, and osmolality; and offer directions for inclusion of solid foods in addition to the formula if necessary.

Usual problems identified in the evaluation will be altered growth, inadequate energy or fluid intakes, drug-nutrient interaction problems, constipation, and feeding problems. Working out an intervention plan is most successful when it involves the parent as part of the team, addresses cultural issues, and recognizes the importance of the feeding problem. Children with CP have complex problems that require continuing follow-up with the family in the community and will take time to correct. There are state agencies that provide tube-feeding formulas and special wheelchairs and equipment to assist with feeding problems. These agencies vary from state to state.

### Autism

Autism is one of five disorders under the category **pervasive developmental disorder (PDD)**. PDD was first used in the 1980s to describe a class of disorders as shown in Table 45-4. All types of PDD are neurologic disorders that are usually evident by age 3. In general, children who have a type of PDD have difficulty in talking, playing with other children, and relating to others, including their families.

### Pathophysiology

**Autism spectrum disorders (ASDs)** are diagnosed by the presence of qualitatively impaired reciprocal social interaction; impaired communication skills; and restricted, repetitive, stereotypical interests and behaviors. Many children with autism also have intellectual compromise. ASD is four times more common in boys than in girls.

**Asperger syndrome** describes children with the problems of ASD but who have normal to high cognitive levels. These children have a difficult time socializing, but may otherwise be able to attend school successfully.

ASDs may occur with other developmental or physical disabilities. They have been associated with tuberous sclerosis and maternal rubella. Macrocephaly has been a common finding in large surveys of individuals with autism and also among their relatives. Overall growth is usually normal, and medical problems nonexistent. However, with the limited variety of foods usually eaten by these children, vitamin and mineral intake could be inadequate.

Efforts to find the cause of ASD have led to many studies looking at a possible toxic environment or food, a nutritionally deficient diet, immune system problems, oxidative stress, and pesticide exposure as important factors. Other studies have studied neurotransmitters such as elevated serotonin levels and disturbances in gamma-amino butyric acid (GABA) receptors, glutamate transmitters, and cholinergic activity. A number of prenatal causes have been evaluated, including pesticides. In one California study (Roberts et al., 2007) women in the first 8 weeks of pregnancy who lived near farm fields sprayed with dicofol and endosulfan were several times more likely to give birth to children with autism. More research is needed with greater numbers of mothers included.

Some treatment and research programs are using genomic panels to identify specific intervention protocols. The genomic panel identifies single-nucleotide polymorphisms,

**TABLE 45-4****Pervasive Developmental Disorders (PDD)**

<b>Disorder</b>	<b>Characteristics</b>
Autistic disorder	Impairment in social interaction Poor communication skills Repetitive and stereotypical behavior
Rett syndrome	Normal until 6-18 months Loss of motor skill abilities Loss of social interaction Deceleration of head growth between 5 and 48 months
Childhood disintegrative disorder	Before age 10 years Loss of expressive language, social skills, bowel or bladder control, play motor skills
Asperger syndrome	Impairment in social interaction Restricted repetitive or stereotypical behavior Normal language development Normal cognitive development
Pervasive developmental disorder not otherwise specified	Deficits in social behavior Impairment in understanding speech and in speech development Does not meet the criteria for the other four disorders

which are identified from blood samples or cell cultures (see Chapter 5). This work has revealed that the child with autism may need additional ω-3 or EFAs; nutrients with antioxidant qualities such as vitamins A, C, E, and selenium; mineral supplementation with zinc, calcium, and magnesium; a mercury-free diet; or an allergy-elimination diet (see Chapter 27).

Interest in a neurochemical cause of ASD has noted gluten and casein as the suspected sources. Intestinal inflammation has been reported in children with ASD and has improved with dietary restriction of gluten and casein (Reichelt and Knivsberg, 2003). Antibodies to casein, gluten, and soy have been noted in some children with ASD.

### Nutrition Assessment

**Anthropometric Measures.** Height and weight are determined for the child and adult with ASD using the equipment and growth charts for nonaffected individuals. Head circumference has been found to be larger than that of the non-ASD individual.

**Biochemical Measures.** There is no standard pattern of tests that should be given other than the regular blood work for health monitoring. However, amino acid screening shortly after birth, thyroid testing, and allergy testing may be indicated (see Chapter 27).

**Dietary Intake.** Evaluations are sometimes difficult to complete for the child with a very limited intake. An effective measure may be provided by having the parents and caregivers keep a food diary for several days to determine the macronutrient intake in addition to the vitamin and mineral intake. See Chapter 4. Obtaining information related to when food is presented and the amount eaten is important, along with fluid consumption. Often excessive

fluids are provided to compensate for limited food consumption.

Evaluations should include an observation of the child during mealtime. Some children are slow in arriving at developmental milestones for self-feeding and require feeding. Others finger feed or insist on self-feeding. The texture of the food presented should be recorded because sensory integration is difficult for children with ASD, and they may be very resistant to texture progression or variety. This is reflected in their fixation on one food (e.g., crackers, dry cereal, or chips). Food jags and picky eating are common. Evaluation should include a description of the feeding environment, whether there is a high chair or age-appropriate toddler chair, the timing of meals, and the location for meals.

### Intervention Strategies

No one therapy or method will work for all individuals with ASD. Many professionals and families use a range of treatments simultaneously, including behavior modification, structured educational approaches, medication, speech therapy, occupational therapy, and counseling. Popular nutrition interventions include mineral and vitamin therapy and elimination diets such as a gluten-free (see Chapter 29), casein-free diet (see Chapter 27); allergy diets (see Chapter 27); supplementation with essential fatty acids (EFAs) and megavitamins.

There are anecdotal reports of success. The exclusion diets are now used in some treatment centers and are publicized on various websites (<http://www.autismndi.com>). Table 45-5 describes some exclusion diets. It is important for the RD to understand these various forms of therapy in order to counsel the parent effectively. Because of the increasing prevalence of ASD, research on potential MNT

**TABLE 45-5****Comparison of Foods Allowed in the Gluten-Free and Casein-Free Diet, Specific Carbohydrate Diet, and Body Ecology Diet**

Food	Gluten- and Casein-Free	Specific Carbohydrate Diet	Body Ecology Diet
Gluten-containing grains (wheat, rye, barley, spelt, kamut, possibly oats) and any products from those grains	Not allowed	Not allowed	Not recommended
Rice	Unlimited	Not allowed	Not recommended
Corn	Unlimited	Not allowed	Some OK if tolerated
Millet, quinoa, amaranth, buckwheat	Unlimited	Not allowed	Unlimited (80/20 rule)*, presoaked
Eggs and meat (beef, fish, lamb, chicken, turkey)	Unlimited	Allowed, processed not permitted	Recommended, organic free range or wild caught preferred, use 80/20 rule*
Vegetables	Unlimited	Fresh or frozen allowed, no canned, no potatoes and yams	Unlimited, fermented vegetables highly recommended
Fruits	Unlimited	Allowed, cooked in initial phase, no canned	Not recommended except lemon, lime, cranberry or black currants; no tomatoes
Milk products	Not allowed	Not initially; then 24-hr goat yogurt, dry curd cottage cheese, specific cheeses and butter	Raw butter and cream initially, kefir in 1 month
Sweeteners	Unlimited	Honey and saccharin	Stevia only
Vinegar	Unlimited	White or apple cider	Raw apple cider only
Juice	Unlimited	Those with no added sugar	Only those from fruits listed previously
Oils	Unlimited	Unlimited	Olive, coconut, pumpkin seed
Condiments	Unlimited	No added sugars, spices	Wheat-free tamari, herbs and spices, Celtic sea salt
Nuts and seeds	Unlimited	Most nuts, no seeds for 3 months	Unlimited raw and soaked
Seaweed	Unlimited	Not allowed	Highly recommended
Beans	Unlimited	After 3 months and soaked 12 hr	Not recommended
Coffee and tea	Unlimited	Allowed weak	Only herb tea or green tea
Coconut products	Unlimited	Fresh only	All recommended
Gelatin	Unlimited	Allowed	Not recommended. Use agar-agar instead

Developed by G. A. Houston-Ludlam. Reprinted with permission from The ANDI News, Autism Network for Dietary Intervention, 2005.

\*80/20 = meal contains: 1) 80% land and ocean vegetables and 20% either protein or a grain and 2) 80% alkaline-forming foods and 20% acid forming foods.

should be promoted. One of the problems with the gluten-, casein-free diet is cost, because special foods needed to provide sufficient food choices are expensive and sometimes difficult to find (see Chapter 27).

When MNT is used, taking a team approach and working with the occupational therapist, speech therapist, and others is important for success. Parents also should be members of the team and counseled that changes will take time. Unfortunately, there have been no double-blind, randomized, controlled studies.

Follow-up is an important component of all therapy. From a nutritional standpoint, routine measures of height and weight should be scheduled, and there should be regular evaluation of eating and feeding behavior related to

increasing ability to self-feed and accept new and different foods.

### Attention-Deficit/Hyperactivity Disorder

**Attention-deficit/hyperactivity disorder (ADHD)** is a neurobehavioral problem seen in children with increasing frequency. It has been associated with learning disorders, inappropriate degrees of impulsiveness, hyperactivity, and attention deficit. Diagnostic criteria were developed by the American Psychiatric Association and have designated three types: (1) combined type of hyperactivity and attention deficit, (2) predominately inattentive type, and (3) predominately hyperactive-impulsive type. ADHD affects the child at home, in school, and in social situations.

## Nutrition Assessment

Many factors should be considered, along with the usual anthropometric measures, particularly when the individual is on medication.

**Anthropometric Measures.** Measurements of height and weight should be taken and recorded on a regular basis because the medications used in treatment may cause anorexia if given at inappropriate times, resulting in inadequate energy intake and potential slowing of growth. A 10 year prospective study of over 250 children with and without ADHD, treated or not treated with medication, found no evidence of limited growth in height over time. (Biederman J et al, 2010).

**Biochemical Measures.** These measurements should include a complete blood count and blood and tissue levels of vitamin and minerals if megavitamin therapy is used.

**Dietary Intake.** A detailed dietary history would include infant feeding history, food likes and dislikes, behavior at mealtimes, snacking behavior, presence of food allergies or food intolerances, or use of special diets. If the individual is on medications, the time of administration in relation to mealtime is important. Information should be obtained regarding any specific diet for the child or individual and how closely it is being followed.

Feeding evaluations should include observing the individual at mealtime. Generally the problems around feeding will be behavioral and will not include oral-motor or positioning peculiarities. Evaluating the environment around mealtime is important because distractions can be problematic.

## Intervention Strategies

Current treatment may include psychotropic medications and the use of consistent behavioral management techniques. The timing and type of medication must be adjusted so that there is minimum influence on the child's dietary intake.

Specific diets have been used for many years, but they are not based on scientific research. For example, parents have been advised to use the Feingold diet, which states that foods containing synthetic food colors and naturally occurring salicylates be removed from the diet because of their neurologic effect.

Recently there has been renewed interest in the role of artificial food colorings (previously advised by Feingold) in exacerbating hyperactivity in selective children. Eight dyes are included: FD&C Blue 1 and 2, FD&C green 3, Orange B, FD&C Red 3, Red 40, FD&C Yellow 5 and 6. The outcome of current interest involves the Food and Drug Administration and committee discussion related to removing food coloring from the food supply (Pelsser LM et al, 2011).

Other recommendations have included the elimination of sugar, the elimination of caffeine, or the addition of large doses of vitamins (megavitamin therapy). A series of well-designed studies to evaluate the effectiveness of these

recommendations have generally had negative results, and successful outcomes are largely anecdotal (see Chapter 18).

For the child or adult who is up and down throughout the meal, behavior modification may be indicated, and it should be a part of the overall behavioral management program. Distractions should be eliminated.

The most effective treatment for the individual with ADHD is a diet based on wholesome foods as outlined in the Dietary Guidelines or MyPlate and in Chapter 12. The food should be served at regular times, with small servings followed by refills. This is an important concept because of the tendency of the child or individual to eat very small amounts and leave the table, planning to return or graze throughout the day. Some programs recommend removing the food and returning it only once after explaining why this is being done. The intervention requires that the child or individual sit at the table in the high chair away from television or other distractions. These suggestions are most applicable to children in preschool settings and in the school cafeteria or classroom.

It has been suggested that a lack of EFAs is a possible cause of hyperactivity in children. It is more likely the result of varying biochemical influences. These children have a deficiency of EFAs because they cannot metabolize linoleic acid normally, they cannot absorb EFAs effectively from the intestine, or their EFA requirements are higher than normal. A recent study in Germany of 810 children ages 5-12 provided a food supplement containing  $\omega$ -3 and  $\omega$ -6 fatty acids plus zinc and magnesium resulting in considerable reduction in attention deficit and hyperactivity after 12 weeks of supplementation (Huss et al., 2010). This type of supplementation can be considered.

## Cleft Lip and Palate

**Cleft lip and cleft palate (CL/CP)** are the most commonly occurring craniofacial birth defects (Merritt, 2005). **Cleft lip** is a condition that creates an opening of the upper lip. It can range from a slight notch to complete separation in one or both sides of the lips, and extending upward. If it occurs on one side of the lip, it is called a *unilateral cleft lip*; if it occurs on both sides, it is called a *bilateral cleft lip*. The **cleft palate** occurs when the roof of the mouth has not joined completely; it can be either unilateral or bilateral. Cleft palate can range from just an opening at the back of the soft palate or separation of the roof of the mouth with both soft and hard palate involved. CL/CP result from incomplete merging and fusion of embryonic processes during formation of the face. There is also a condition called *submucous cleft palate* in which there is incomplete fusion of the muscular layers of the soft palate with fusion of the overlying mucosa (Figures 45-5 and 45-6).

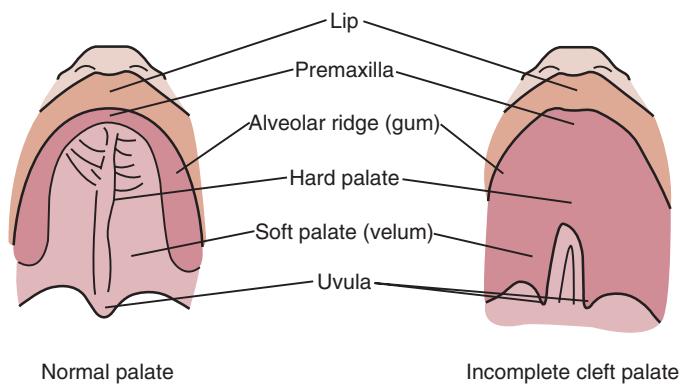

Lip and palate development occur between 5 and 12 weeks of gestation. Lip development begins first, usually at 5 weeks of gestation, followed by the development of the maxilla prominences and the primary palate. Fusion of the hard palate is completed by 10 weeks of gestation and the soft palate by 12 weeks.

The incidence of CL/CP varies but is generally 1 in 700 live births. CL/CP have multiple causes and are often associated with underlying syndromes such as Pierre Robin sequence. The Pierre Robin syndrome or complex is a birth condition that involves the lower jaw being either small in size (micrognathia) or set back from the upper jaw (retrognathia) (Cleft Palate Foundation, 2006). As a result, the tongue tends to be displaced back toward the throat, where it can fall back and obstruct the airway. Most infants will have a cleft palate, but none will have a cleft lip. The incidence of Pierre Robin ranges from 1 in 2000 to 30,000 births, based on how strictly the diagnosis is made. The basic cause appears to be the failure of the lower jaw to develop normally before birth.

Approximately 50% of children with cleft palate have an underlying syndrome or multiple anomalies. Wide ranges of studies in developmental biology have shown that both genetics and environmental factors are involved in causing oral clefts. Some of the risk factors from the environment include maternal folic acid deficiency, smoking, alcohol use, anticonvulsant use, and some maternal illnesses. Genetic counseling can now identify high-risk families.

### Nutrition Assessment

Nutrition assessment for CL/CP includes the usual anthropometric measures for all infants and children. Biochemical measures are also those used with nonaffected children,

**FIGURE 45-5** Cleft palate. (From the Cleft Palate Foundation. Accessed 28 December 2006 from [www.cleftline.org](http://www.cleftline.org).)

**FIGURE 45-6** Cleft lip. (From the Cleft Palate Foundation. Accessed 28 December 2006 from [www.cleftline.org](http://www.cleftline.org).)

and dietary intake information depends on the feeding problems that exist. Other problems include dental abnormalities and missing teeth, speech difficulties, and increased incidence of middle ear infections. The feeding evaluation is a major part of the assessment and is best accomplished with a team approach, including the parents. Because the major problem in CL/CP is feeding and providing adequate intake, growth can be jeopardized and needs to be assessed regularly.

### Intervention Strategies

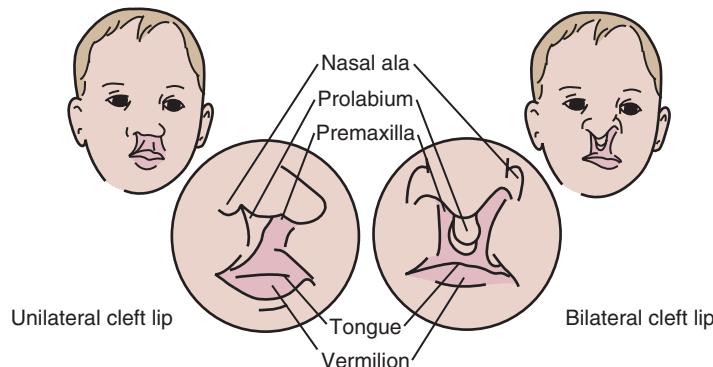

Surgical repair of the cleft lip is generally done at 2 to 3 months of age, and cleft palate repair at 9 months. Other operations may involve minor improvements to the lip or nose and are usually completed before the child starts school.

Breast-feeding is difficult for these infants because of problems with sucking, although those infants with just the cleft lip may be successful. It is generally recommended that the mother who wishes to breast-feed express her milk and give it to her baby from a specialized bottle and nipple. Parents and caregivers need to be educated in the positioning of the child for feeding, nipple selection, bottle selection, and monitoring of intake.

Energy needs are generally the same as for a nonaffected infant or child, but, if the feeding process is too difficult, the energy needs may not be met. Strategies for solving that problem vary, with some professionals advising tube feeding, whereas others recommend continuing with appropriate bottles and nipples but using more concentrated formula or breast milk; see Chapter 43 and Table 45-6.

Effective feeding requires that the infant be able to form a vacuum inside the mouth and form a seal around the nipple with the lips. This is achieved through the proper bottle, nipple, and position for feeding. Some of the acceptable nipples and bottles include a regular newborn nipple with enlarged holes, a lamb's nipple, a Ross cleft palate assembly, an obturator nipple, and the orthodontic vented nipple. Bottles can vary from a very soft bottle with a cross-cut nipple to a Haberman feeder, squeeze bottle, or an Asepto feeder.

Individuals with CL/CP are different; thus it is extremely important that the feeding team evaluate various types of equipment and carefully educate the parent in their use.

**TABLE 45-6****Increasing Calories through Concentration of Formulas and Addition of Oils and Carbohydrates**

<b>Using 20 cal/oz Formula</b>		<b>Caloric Density Required Per Ounce</b>	<b>Measures of Powder</b>	<b>Water Added</b>
20 calories		1 scoop	2 oz	
22 calories		2 scoops	3.5 fl oz	
24 calories		3 scoops	5 fl oz	
27 calories		3 scoops	4.25 fl oz	
<b>Using 22 cal/oz Formula</b>				
22 cal		1 scoop	2 fl oz	
24 cal		3 scoops	5.5 fl oz	
27 cal		5 scoops	8 fl oz	
<b>Adding Oil or Carbohydrates</b>				
<b>Product</b>	<b>kcal</b>	<b>Source</b>		
Corn oil or safflower oil	9/g or 8.3/mL	Corn or safflower oil		
Microlipid	4.5/mL	Safflower oil		
MCT oil	8.3/g or 7.6/mL	Fractionated coconut oil		
Karo syrup	1 Tbsp = 58 kcal	Polysaccharides		
Polycose liquid	2/mL or 60/fl oz	Glucose polymers		
Polycose powder	3.8/g; 8/tsp; 23/Tbsp	Glucose polymers		
Modulcal powder	30/Tbsp	Glucose polymers		

*MCT*, Medium-chain triglyceride.

Palate obturators have been used to cover the cleft palate until the child can have surgery to close it; their use results in improved intake, better feeding skills, increased weight gain, and growth of the dental arches. Disadvantages include cost and the inconvenience of refabricating the devices as the infant grows to maintain effectiveness. One study (Prahl et al., 2005) measured growth and the length of feeding between two groups, one using the obturator and one without, and found no significant difference in growth, leading the researchers to conclude that the obturator could be abandoned. Positioning in an upright position, choosing the appropriate nipple, and directing the liquid flow to the side or back of the mouth seem to be just as effective in promoting optimal feeding and are recommended. The baby should be given ample opportunities for frequent burping in an upright position.

Introduction of solid foods for the CL/CP infant can follow the usual protocol at 4 to 6 months of age. By this time the cleft lip should have been repaired, and the child has achieved good head control and trunk stability. Care needs to be taken that the food is presented slowly, allowing

the infant to control each bite while gradually learning how to direct the food around the cleft until it is repaired. Following the repair and healing of the cleft palate, feeding along the developmental pathway should progress slowly but normally. See Chapter 17.

**FETAL ALCOHOL SYNDROME**

**Fetal alcohol syndrome (FAS)** is a pattern of mental and physical defects that can develop in the fetus of a woman who drinks alcohol during pregnancy. The effects of the alcohol consumption include growth retardation and usually characteristic facial stigmata, damaged neurons and brain structures which can result in psychological or behavioral problems and other physical problems. The prevalence rate in the US and Europe is estimated to be between 0.2-1.5 in every 1000 live births. FAS was named in 1973 by Drs. Kenneth Jones and David Smith at the University of Washington School of Medicine after identifying a pattern of craniofacial, limb and cardiovascular defects in eight unrelated children of three ethnic groups all born to women who were alcoholics (Jones, KL, et al, 1973).

Diagnosis of fetal alcohol syndrome requires that the following criteria are fully met: 1) growth deficiency, 2) FAS facial features, 3) central nervous system damage, and 4) prenatal alcohol exposure. The three facial features include smooth filtrum (the groove between the upper lip and the nose; thin upper lip; small palpebral (between the upper and lower eyelid) fissures. See Fig. 16-4 on p. 361.

**Nutrition Assessment**

Anthropometric measures are very important in the assessment of the FAS child since growth deficiency is part of the diagnosis. In severe growth deficiency both the height and weight are below the 3rd percentile, while in moderate cases of growth deficiency, either the height or weight is below the 3rd percentile, but not both. Growth should be evaluated frequently and plotted on the CDC and WHO growth curves. Studies have shown that the prenatal growth retardation of the infant may persist postnatally and some infants have failure to thrive. (Huber A, Ekvall S. 2005). Feeding problems have also been associated with FAS, including having a weak suck and oral motor problems, making these babies difficult to feed. This would contribute to failure to thrive.

**Intervention Strategies**

Nutritional intervention for the child with FAS is focused on the specific nutrition problem that exists for that child. Working with growth deficiency, failure to thrive and feeding problems requires the usual evaluation and intervention used in other infants and children with developmental disabilities. Energy and nutrient needs are the same as for non-affected children, although strategies for increasing calories would be required for those who have failure to thrive. For some children ADHD has been reported, and the treatment should be the same as already described.

## CONTROVERSIAL NUTRITION THERAPY

An important factor in providing MNT for children and adults with developmental disabilities is realizing that counseling may have been inadequate in helping the parent accept the limitations of the disorder, limitations such as growth, feeding problems, and cognitive ability. As a result, many parents look for unusual medical or nutrition therapies. Major sources of information are often the Internet and parent support groups. Recent media coverage has promoted the use of antioxidant vitamins (A, C, and E) and minerals (zinc, copper, manganese, and selenium) along with the amino acids glucosamine, tyrosine, and tryptophan. The expected outcomes are improved growth; increased cognition, alertness, and attention span; and changed facial features.

There is little scientific information to back up these therapies. Research studies have addressed the vitamin needs of children with DS, spina bifida, fragile X syndrome, and autism, and findings do not indicate that the vitamin and mineral needs of these children with developmental disabilities are higher than normal. Numerous historical studies have searched for nutritional deficiencies as causative factors in DS. Traditionally, the studies have included numerous vitamins, minerals, fatty acids, digestive enzymes, lipotropic nutrients, and numerous drugs, with no definitive results.

The key concept in the proposed nutrition interventions for DS is metabolic correction of genetic overexpression. It is postulated that presence of the third chromosome 21

causes overproduction of superoxide dismutase and cystathione *b*-synthase, which disrupts active methylation pathways. Vitamin supplements of folic acid and antioxidants counteract this and are considered key to the treatment. However, these are just theories, and at this point nutrition supplements are considered an expensive, questionable approach.

Parents of children with ADHD report that omitting sugar from the children's diets decreases hyperactivity, but there is no scientific evidence to support this. However, it probably is a good idea to eliminate or at least reduce the sugar intake in any child's diet to promote better nutritional intake. Blue-green algae has been promoted for children with DS and other developmental disabilities, purportedly to increase attention span and concentration. High-dose supplementation of vitamin B<sub>6</sub> and magnesium has been proposed for autism to diminish tantrums and self-stimulation activities and improve attention and speech. Another proposed treatment is dimethyl glycine. Limited research is available.

## COMMUNITY RESOURCES

For many types of nutrition problems and MNT, the school system is an excellent resource through the school lunch and school breakfast programs. Children and adolescents may receive modified meals at school. Child and adult care food programs must provide meals at no extra cost for children and adolescents with special needs and developmental disabilities. School food service is required to offer special

<b>Name of student for whom special meals at school are requested:</b>	
<b>Disability or medical condition that requires the student to have a special diet. Include a brief description of the major life activity affected by the student's condition.</b>	
<b>Foods omitted and substitutions</b> (Please check food groups to be omitted. List specific foods to be omitted and suggest substitutions using the back of this form or attach information.)	
• Meat and meat alternatives • Milk and milk products • Bread and cereal products • Fruits and vegetables

meals at no additional cost to children whose disabilities restrict their diets as defined in the U.S. Department of Agriculture's nondiscrimination regulations.

The term "child with a disability" under Part B of the Individuals with Disabilities Education Act (IDEA) refers to a child evaluated in accordance with IDEA as having one of the 13 recognized disability categories: (1) autism; (2) deaf-blindness; (3) deafness; (4) mental retardation; (5) orthopedic impairments; (6) other health impairments caused by chronic or acute health problems such as asthma, nephritis, diabetes, sickle cell anemia, a heart condition, epilepsy, rheumatic fever, hemophilia, leukemia, lead poisoning, or tuberculosis; (7) emotional disturbances; (8) specific learning

disabilities; (9) speech or language impairment; (10) traumatic brain injury; (11) visual impairment; (12) multiple disabilities; and (13) developmental delays. Attention deficit disorder may fall under 1 of the 13 categories.

When a referral is made to the school system for a special meal related to a developmental disability, it must be accompanied by a medical statement for a child with special dietary needs (Figure 45-7). The request requires an identification of the medical or other special dietary condition, the food or foods to be omitted, and the food or choice of foods to be substituted. The statement requires the signature of the physician or recognized medical authority. The school food service may make food substitutions for individual children

## CLINICAL SCENARIO 1

**M**itchell is a 2-month-old boy with Down syndrome. He was born prematurely (30 weeks of gestation) and was started on gastrostomy tube feeding at 10 days of age because of his poor weight gain and severe gastroesophageal reflux. The poor weight gain was caused by a poor suck, although swallowing was not a problem. He was first seen by a nutritionist in an early intervention program at 4 months of age when he was 22.5 in long and weighed 10 lb 7 oz.

At 16 months he started eating table foods, and his tube-feeding formula was PediaSure. By 21 months his height was 28 inches, and his weight 18.5 lb. He was at the 5th percentile for length and weight using the CDC growth curves, but at the 25th percentile when the Down syndrome curves were used. He had been taking oral feeds since 7 months of age, but his total oral consumption was one jar of baby food a day in addition to his gastrostomy feeds. He was crawling but not yet walking, and he had very limited self-feeding skills. Now at age 21 months his mother's highest priority is to stop the tube feeding and have Mitchell continue to grow well; she is concerned about his rate of weight gain. She is

also concerned that constipation has become a problem requiring medication.

### Nutrition Diagnostic Statement

Self-feeding difficulty related to developmental delays as evidenced by inability to feed self most foods offered.

### Nutrition Care Questions

1. What would be your approach in working with this mother and the other team members?
2. What do you think would be his nutritional needs, starting with energy?
3. How many ounces of a 30 cal/oz tube-feeding formula would you recommend for Mitchell to promote weight gain?
4. What steps should be taken to increase his oral intake and decrease the tube feeding?
5. What would you recommend for management of his constipation?

## CLINICAL SCENARIO 2

**L**uke is a 2-year-old boy with Prader-Willi syndrome. He was born weighing 7 lb and was 18 in long. A test done in the nursery determined that he had Prader-Willi syndrome. Typical of Prader-Willi syndrome, Luke was a very hypotonic infant with a very poor suck. Mom wanted to breast-feed, but Luke was unable to latch on at the breast, so she pumped her milk. Also it was recommended that human milk fortifier (HMF) be added to the breast milk. She was very concerned about adding the HMF because she had read about potential obesity as Luke grew older. After discharge from the hospital Luke entered an early intervention program with nutrition services. Eventually the mother changed Luke to an infant formula, but Luke continued to have a weak suck, and feeding services were needed.

### Nutrition Diagnostic Statement

Inability to feed self related to weak suck and hypotonia as evidenced by need for feeding services.

### Nutrition Care Questions

1. What would be a good plan for continuing nutrition care for Luke?
2. What kind of information should the nutritionist provide to the mother related to her fear of eventual obesity for Luke?
3. As Luke grows older, what would be a good way to determine the number of calories he should receive to prevent obesity?

who do not have a disability but who are medically certified as having a special medical or dietary need. An example is the child with severe allergies or an inborn error of metabolism. The availability of school food service for children with developmental disabilities is an important resource in the long-term implementation of MNT.

- 58.** Nutritional Facts on Zinc, 1164

---

**Nutritional Facts\*** (Appendices 38–58) unless otherwise noted created from the North Carolina Dietetic Association: Nutrition care manual, 2011, Raleigh, North Carolina; USDA Agricultural Research Service, Nutrient Data Laboratory, accessed March 2011 from <http://www.nal.usda.gov/fnic/foodcomp/search/>. Compiled by Maria Balance, MS, RD, LDN.

## APPENDIX 1. Medical Abbreviations

ABGs	arterial blood gases	FTT	failure to thrive
ACTH	adrenocorticotrophic hormone	Fx	fracture
AD	Alzheimer's disease	GB	gallbladder
ADH	antidiuretic hormone	GFR	glomerular filtration rate
ADI	adequate daily intake	GI	gastrointestinal
ADIME	assessment, diagnosis, intervention, monitoring, evaluation	GIP	gastric inhibitory polypeptide
ADLs	activities of daily living	GTF	glucose tolerance factor
AI	adequate intake	GTT	glucose tolerance test
AIDS	acquired immunodeficiency syndrome	GVHD	graft-versus-host disease
ALA	$\alpha$ -linolenic acid	HAV	hepatitis A virus
ALS	amyotrophic lateral sclerosis	Hgb	hemoglobin
AP	angina pectoris	HBV	hepatitis B virus
ARF	acute renal failure	HCT	hematocrit
ASHD	atherosclerotic heart disease	HDL	high-density lipoprotein
ATP	adenosine triphosphate	HE	hepatic encephalopathy
BCAA	branched-chain amino acid	HF	heart failure
BEE	basal energy expenditure	Hgb	hemoglobin
BHA	butylated hydroxyanisole	H&D	history and physical
BHT	butylated hydroxytoluene	HIV	human immunodeficiency virus
BMI	body mass index	HPN	home parenteral nutrition
BMR	basal metabolic rate	HSL	hormone-sensitive lipase
BMT	bone marrow transplantation	HTN	hypertension
BPD	bronchopulmonary dysplasia	Hx	history
BSA	body surface area	IBD	inflammatory bowel disease
BV	biologic value	IBS	irritable bowel syndrome
CA	cancer	IBW	ideal body weight
CAD	coronary artery disease	ICU	intensive care unit
CAPD	continuous ambulatory peritoneal dialysis	IF	intrinsic factor
CAVH	continuous arteriovenous hemofiltration	IgE	immunoglobulin E
CCK	cholecystokinin	IGT	impaired glucose tolerance
CCU	coronary care unit	IL-2	interleukin-2
CDC	Centers for Disease Control and Prevention	IM	intramuscular
CHD	coronary heart disease	INH	isonicotinic acid hydrazide
CHI	closed head injury	INR	international normalized ratio
CKD	chronic kidney disease	I&O	intake and output
CNS	central nervous system	IV	intravenous
COPD	chronic obstructive pulmonary disease	J	joule
CPN	central parenteral nutrition	kcal (Cal)	kilocalorie
CSII	continuous subcutaneous insulin infusion	kJ	kilojoule
CSF	cerebrospinal fluid	KUB	kidney, ureter, bladder
CVA	cerebrovascular accident	LBM	lean body mass
DCCT	Diabetes Control and Complications Trial	LCT	long-chain triglyceride
DHA	docosahexaenoic acid	LDL	low-density lipoprotein
DHHS	Department of Health and Human Services	LES	lower esophageal sphincter
DJD	degenerative joint disease	LFT	liver function test
DKA	diabetic ketoacidosis	LPL	lipoprotein lipase
DM	diabetes mellitus	MAOI	monoamine oxidase inhibitor
DNA	deoxyribonucleic acid	MCH	mean corpuscular hemoglobin
DRI	dietary reference intake	MCT	medium-chain triglyceride
ECG/EKG	electrocardiogram	MCV	mean corpuscular volume
EDTA	ethylenediaminetetraacetate	MDS	minimum data set
EFA	essential fatty acid	MET	metabolic equivalent
EPA	eicosapentaenoic acid	MFOS	mixed-function oxidase system
EPO	erythropoietin	MI	myocardial infarction
ERT	estrogen replacement therapy	MSG	monosodium glutamate
ESR	erythrocyte sedimentation rate	MSUD	maple syrup urine disease
ESRD	end-stage renal disease	NANB	non-A, non-B hepatitis virus
FAD	flavin adenine dinucleotide	NCEP	National Cholesterol Education Program
FBG	fasting blood glucose	NCP	Nutrition Care Process
FBS	fasting blood sugar	NG	nasogastric
FFA	free fatty acid	NPO	nothing by mouth
FIGLU	formiminoglutamic acid	NPU	net protein utilization
FMN	flavin mononucleotide	NSAID	nonsteroidal antiinflammatory drug
FPG	fasting plasma glucose	NSP	nonstarch polysaccharide
		N&V	nausea and vomiting

Continued

## APPENDIX 1. Medical Abbreviations—cont'd

OCA	oral contraceptive agent	ROS	review of systems
OGTT	oral glucose tolerance test	RQ	respiratory quotient
OHA	oral hypoglycemic agent	RTA	renal tubular acidosis
PBI	protein-bound iodine	SCA	sickle cell anemia
PCM	protein-calorie malnutrition	SCT	short-chain triglycerides
PEG	percutaneous endoscopic gastrostomy	SFA	saturated fatty acid
PEM	protein-energy malnutrition	SLE	systemic lupus erythematosus
PER	protein efficiency ratio	SMBG	self-monitoring of blood glucose
PG	prostaglandin	SOB	shortness of breath
PHE	phenylalanine	S/P	status post
PKU	phenylketonuria	TBSA	total body surface area
PLP	pyridoxal phosphate	TC	total cholesterol
PN	parenteral nutrition	TEE	total energy expenditure
PPN	peripheral parenteral nutrition	TEF	thermic effect of food
PRN	as needed	TG	triglyceride or triacylglycerol
PT	patient	THF	tetrahydrofolate
PTA	prior to admission	TIA	transient ischemic attack
PTT	partial thromboplastin time	TIBC	total iron-binding capacity
PUD	peptic ulcer disease	TNF	tumor necrosis factor
PUFA	polyunsaturated fatty acid	TS	transferrin saturation
RAST	radioallergosorbent test	UL	upper intake level
RBC	red blood cell	URI	upper respiratory infection
RDA	recommended dietary allowance	UTI	urinary tract infection
RDS	respiratory distress syndrome	VLCD	very-low-calorie diet
REE	resting energy expenditure	VLDL	very-low-density lipoprotein
RMR	resting metabolic rate	VOD	venous occlusive disease
RNA	ribonucleic acid	VS	vital signs
R/O	rule out	WNL	within normal limits

## APPENDIX 2. Unit Abbreviations

Along with the specialized vocabulary that is used in the medical, dietetic, and nursing fields, there are acceptable forms of abbreviations. The following is a list of abbreviations commonly used.

aa: Gr. *ana*; of each  
 ac: L. *ante cibum*; before meals  
 ad, add: L. *adde, addatus, or addantur*; add or added  
 ad lib: L. *ad libitum*; at pleasure, as desired  
 aq: L. *aqua*; water  
 aq dest: L. *aqua destillata*; distilled water  
 bid, bis in d: L. *bis in die*; twice a day  
 c: L. *cum*; with  
 c: cup  
 Cent; cent; C: centigrade, Celsius  
 cm: centimeter  
 dilut: L. *dilutus*; dilute  
 div: L. *divide*; divide  
 fac: make  
 g: gram  
 gr: L. *granum*; grain  
 gt: L. *guttae*; drops  
 hs: L. *hora somni*; at hour of sleep  
 IU: international unit  
 kcal: kilocalorie  
 kg: kilogram  
 kJ: kilojoule  
 lb: pound  
 mcg: microgram

mEq: milliequivalent  
 mg: milligram  
 mil or mL: milliliter  
 mM: millimole  
 µmol: micromol  
 mOsm: milliosmole  
 oz: ounce  
 prn: L. *pro re nata*; may be repeated according to instructions  
 pt: pint  
 pulv: L. *pulvis*; powder  
 qd: L. *quaque die*; every day  
 QID, qid: L. *quater in die*; four times daily  
 q3h: every 3 hours  
 qs: L. *quantum satis*; a sufficient quantity  
 qt: quart  
 RE: retinal equivalent  
 s: L. *sine*; without  
 sol: solution  
 ss: L. *semis*; half  
 stat: L. *statim*; immediately  
 T, tsp: teaspoon  
 T, Tbsp: tablespoon  
 tid: L. *ter in die*; three times a day

### APPENDIX 3. Milliequivalents and Milligrams of Electrolytes

**To Convert Milligrams to Milliequivalents:** Divide milligrams by atomic weight and then multiply by the valence.

$$\text{Example: } \frac{\text{Milligrams}}{\text{Atomic weight}} \times \text{Valence} = \text{Milliequivalents}$$

Mineral Element	Chemical Symbol	Atomic Weight (mg)	Valence
Calcium	Ca	40	2
Chlorine	Cl	35	1
Magnesium	Mg	24	2
Phosphorus	P	31	2
Potassium	K	39	1
Sodium	Na	23	1
Sulfate	SO <sub>4</sub>	96	2
Sulfur	S	32	

**To Convert Specific Weight of Sodium to Sodium Chloride:** Multiply by 2.54.

$$\text{Example: } 1000 \text{ mg Sodium} = 1000 \times 2.54 \\ = 2540 \text{ mg Sodium chloride (2.5 g)}$$

**To Convert Specific Weight of Sodium Chloride to Sodium:** Multiply by 0.393.

$$\text{Example: } 2.5 \text{ g Sodium chloride} = 2.5 \times 0.393 \\ = 1000 \text{ mg sodium}$$

Milligrams	Sodium in Milliequivalents (mEq)	Grams of Sodium Chloride
500	21.8	1.3
1000	43.5	2.5
1500	75.3	3.8
2000	87.0	5.0

Modified from Merck Manual, Ready Reference Guide. Accessed 22 March 2011 from <http://www.merckmanuals.com/professional/print/appendices/ap1/ap1a.html>; Nelson JK et al: Mayo Clinic diet manual, ed 7, St Louis, 1994, Mosby.

### APPENDIX 4. Equivalents, Conversions,\* and Portion (Scoop) Sizes

#### Liquid Measure—Volume Equivalents

1 tsp =  $\frac{1}{3}$  Tbsp = 5 mL or cc  
 1 Tbsp = 3 tsp = 15 mL or cc  
 2 Tbsp = 1 fluid oz =  $\frac{1}{8}$  cup = 30 mL or cc  
 2 Tbsp + 2 tsp =  $\frac{1}{4}$  cup = 40 mL or cc  
 4 Tbsp =  $\frac{1}{4}$  cup = 2 fluid oz = 60 mL or cc  
 5 Tbsp + 1 tsp =  $\frac{1}{2}$  cup = 80 mL or cc  
 6 Tbsp = 3 fluid oz =  $\frac{3}{4}$  cup = 90 mL or cc  
 8 Tbsp =  $\frac{1}{2}$  cup = 120 mL or cc  
 10 Tbsp + 2 tsp =  $\frac{1}{2}$  cup = 160 mL or cc  
 12 Tbsp =  $\frac{3}{4}$  cup = 180 mL or cc  
 48 tsp = 16 Tbsp = 1 cup (8 fluid ounces) =  $\frac{1}{2}$  pint = 240 mL or cc  
 2 cups = 1 pint (16 fluid oz) = 0.4732 L  
 4 cups = 2 pints = 1 quart (32 fluid oz) = 0.9462 L  
 1.06 quarts = 34 fluid oz = 1000 mL or cc  
 4 quarts = 1 gallon = 3785 mL or cc

#### Dry Measure

1 quart = 2 pints = 1.101 L  
 Dry measure and quarts are approximately  $\frac{1}{6}$  larger than liquid measure pints and quarts.

#### Weights

English (Avoirdupois)	Metric
1 oz	Approx 30 g
1 lb (16 oz)	454 g
2.2 lb	1 kg

#### Scoop Sizes

It is important to use the proper scoop size when portioning out foods to serve to patients. The dietitian will be expected to know and guide staff accordingly.

Number	Approximate Liquid Volume
6	$\frac{1}{3}$ cup (5 fluid oz)
8	$\frac{1}{2}$ cup (4 fluid oz)
10	$\frac{3}{8}$ cup ( $3\frac{1}{4}$ fluid oz)
12	$\frac{1}{2}$ cup ( $2\frac{1}{2}$ fluid oz)
16	$\frac{1}{4}$ cup (2 fluid oz)
20	$3\frac{1}{2}$ Tbsp (1 $\frac{1}{2}$ fluid oz)
24	$2\frac{1}{2}$ Tbsp (1 $\frac{1}{2}$ fluid oz)
30	$2\frac{1}{2}$ Tbsp (1 fluid oz)
40	$1\frac{1}{2}$ Tbsp (0.8 fluid oz)
60	1 Tbsp (0.5 fluid oz)

#### Metric Conversion Factors

Multiply	By	To Get
Fluid ounces	29.57	Grams
Ounces (dry)	28.35	Grams
Grams	0.0353	Ounces
Grams	0.0022	Pounds
Kilograms	2.21	Pounds
Pounds	453.6	Grams
Pounds	0.4536	Kilograms
Quarts	0.946	Liters
Quarts (dry)	67.2	Cubic inches
Quarts (liquid)	57.7	Cubic inches
Liters	1.0567	Quarts
Gallons	3.785	Cubic centimeters
Gallons	3.785	Liters

From North Carolina Dietetic Association: Nutrition care manual, 2011, Raleigh, NC, The Association.

\*Note: In the U.S. measuring systems the same word may have two meanings. For example, an ounce may mean  $\frac{1}{16}$  of a pound and  $\frac{1}{16}$  of a pint; but the former is strictly a weight measure, and the latter is a volume measure. Except in the case of water, milk, or other liquids of the same density, a fluid ounce and an ounce of weight are two completely different quantities. These measures are not to be used interchangeably.

## APPENDIX 5. Focus on Nutrition Care Process: Nutrition Assessment

**Step 1. Nutrition assessment** is designed to identify nutrition-related problems and their causes. A nutrition assessment matrix links nutrition assessment parameters with nutrition diagnoses.

### Nutrition Assessment and Monitoring and Evaluation Terminology

This is a combined list of Nutrition Assessment and Monitoring and Evaluation terms. Indicators that are shaded are used ONLY for nutrition assessment. The rest of the indicators are used for assessment and monitoring and evaluation.

#### FOOD/NUTRITION-RELATED

##### (FH)

*Food and nutrient intake, food and nutrient administration, medication/herbal supplement use, knowledge/beliefs/attitudes, behavior, food and supply availability, physical activity and function, nutrition-related patient/client-centered measures.*

##### Food and Nutrient Intake (1)

*Composition and adequacy of food and nutrient intake, and meal and snack patterns.*

##### Energy Intake (1.1)

*Total energy intake from all sources, including food, beverages, supplements, and via enteral and parenteral routes.*

##### Energy intake (1.1.1)

Total energy intake FH-1.1.1.1

##### Food and Beverage Intake (1.2)

*Type, amount, and pattern of intake of foods and food groups, indices of diet quality, intake of fluids, breast milk and infant formula*

##### Fluid/beverage intake (1.2.1)

Oral fluids FH-1.2.1.1  
 Food-derived fluids FH-1.2.1.2  
 Liquid meal replacement or supplement FH-1.2.1.3

##### Food intake (1.2.2)

Amount of food FH-1.2.2.1  
 Types of food/meals FH-1.2.2.2  
 Meal/snack pattern FH-1.2.2.3  
 Diet quality index FH-1.2.2.4  
 Food variety FH-1.2.2.5

##### Breast milk/infant formula intake (1.2.3)

Breast milk intake FH-1.2.3.1  
 Infant formula intake FH-1.2.3.2

##### Enteral and Parenteral Nutrition Intake (1.3)

*Specialized nutrition support intake from all sources, e.g., enteral and parenteral routes.*

##### Enteral nutrition intake (1.3.1)

Formula/solution FH-1.3.1.1  
 Feeding tube flush FH-1.3.1.2

##### Parenteral nutrition intake (1.3.2)

Formula/solution FH-1.3.2.1  
 IV fluids FH-1.3.2.2

##### Bioactive Substance Intake (1.4)

*Alcohol, plant stanol and sterol esters, soy protein, psyllium and β-glucan, and caffeine intake from all sources, e.g., food, beverages, supplements, and via enteral and parenteral routes.*

##### Alcohol intake (1.4.1)

Drink size/volume FH-1.4.1.1  
 Frequency FH-1.4.1.2  
 Pattern of alcohol consumption FH-1.4.1.3

##### Bioactive substance intake (1.4.2)

Plant sterol and stanol esters FH-1.4.2.1  
 Soy protein FH-1.4.2.2  
 Psyllium and β-glucan FH-1.4.2.3  
 Food additives (specify) FH-1.4.2.4  
 Other (specify) FH-1.4.2.5

##### Caffeine intake (1.4.3)

Total caffeine FH-1.4.3.1

##### Macronutrient Intake (1.5)

*Fat and cholesterol, protein, carbohydrate, and fiber intake from all sources including food, beverages, supplements, and via enteral and parenteral routes.*

#### Fat and cholesterol intake (1.5.1)

- Total fat FH-1.5.1.1
- Saturated fat FH-1.5.1.2
- Trans fatty acids FH-1.5.1.3
- Polyunsaturated fat FH-1.5.1.4
- Monounsaturated fat FH-1.5.1.5
- Omega-3 fatty acids FH-1.5.1.6
- Dietary cholesterol FH-1.5.1.7
- Essential fatty acids FH-1.5.1.8

#### Protein intake (1.5.2)

- Total protein FH-1.5.2.1
- High biological value protein FH-1.5.2.2
- Casein FH-1.5.2.3
- Whey FH-1.5.2.4
- Amino acids FH-1.5.2.5
- Essential amino acids FH-1.5.2.6

#### Carbohydrate intake (1.5.3)

- Total carbohydrate FH-1.5.3.1
- Sugar FH-1.5.3.2
- Starch FH-1.5.3.3
- Glycemic index FH-1.5.3.4
- Glycemic load FH-1.5.3.5
- Source of carbohydrate FH-1.5.3.6
- Insulin-to-carbohydrate ratio FH-1.5.3.7

#### Fiber intake (1.5.4)

- Total fiber FH-1.5.4.1
- Soluble fiber FH-1.5.4.2
- Insoluble fiber FH-1.5.4.3

#### Micronutrient Intake (1.6)

*Vitamin and mineral intake from all sources, e.g., food, beverages, supplements, and via enteral and parenteral routes.*

#### Vitamin intake (1.6.1)

- A (1)  Riboflavin (7)
- C (2)  Niacin (8)
- D (3)  Folate (9)
- E (4)  B6 (10)
- K (5)  B12 (11)
- Thiamin (6)  Multivitamin (12)
- Other (specify) \_\_\_\_\_ (13)

#### Mineral/element intake (1.6.2)

- Calcium (1)  Potassium (5)
- Chloride (2)  Phosphorus (6)
- Iron (3)  Sodium (7)
- Magnesium (4)  Zinc (8)
- Multi-mineral (9)
- Multi-trace element (10)
- Other, (specify) \_\_\_\_\_ (11)

#### Food and Nutrient Administration (2)

*Current and previous diets and/or food modifications, eating environment, and enteral and parenteral nutrition administration.*

#### Diet History (2.1)

*Description of food and drink regularly provided or consumed, past diets followed or prescribed and counseling received, and the eating environment.*

#### Diet order (2.1.1)

- General, healthful diet FH-2.1.1.1
- Modified diet FH-2.1.1.2  
(specify) \_\_\_\_\_
- Enteral nutrition order FH-2.1.1.3  
(specify) \_\_\_\_\_
- Parenteral nutrition order FH-2.1.1.4  
(specify) \_\_\_\_\_

#### Diet experience (2.1.2)

- Previously prescribed diets FH-2.1.2.1
- Previous diet/nutrition education/counseling FH-2.1.2.2
- Self-selected diet/s followed FH-2.1.2.3
- Dieting attempts FH-2.1.2.4

#### Eating environment (2.1.3)

- Location FH-2.1.3.1
- Atmosphere FH-2.1.3.2
- Caregiver/companion FH-2.1.3.3
- Appropriate breastfeeding accommodations/facility FH-2.1.3.4
- Eats alone FH-2.1.3.5

#### Enteral and parenteral nutrition administration (2.1.4)

- Enteral access FH-2.1.4.1
- Parenteral access FH-2.1.4.2

#### Medication and Herbal Supplement Use (3)

*Prescription and over-the counter medications, including herbal preparations and complementary medicine products used.*

#### Medication and herbal supplements (3.1)

- Medications, specify prescription or OTC
- Herbal/complementary products (specify)
- Misuse of medication (specify) FH-3.1.3

#### Knowledge/Beliefs/Attitudes (4)

*Understanding of nutrition-related concepts and conviction of the truth and feelings/emotions toward some nutrition-related statement or phenomenon, along with readiness to change nutrition-related behaviors.*

#### Food and nutrition knowledge (4.1)

- Area(s) and level of knowledge FH-4.1.1
- Diagnosis specific or global nutrition-related knowledge score FH-4.1.2

#### Beliefs and attitudes (4.2)

- Conflict with personal/family value system FH-4.2.1
- Distorted body image FH-4.2.2
- End-of-life decisions FH-4.2.3
- Motivation FH-4.2.4
- Preoccupation with food/nutrients FH-4.2.5
- Preoccupation with weight FH-4.2.6
- Readiness to change nutrition-related behaviors FH-4.2.7
- Self-efficacy FH-4.2.8
- Self-talk/cognitions FH-4.2.9
- Unrealistic nutrition-related goals FH-4.2.10
- Unscientific beliefs/attitudes FH-4.2.11
- Food preferences (specify) FH-4.2.12
- Emotions (specify) FH-4.2.13

#### Behavior (5)

*Patient/client activities and actions, which influence achievement of nutrition-related goals.*

#### Adherence (5.1)

- Self-reported adherence score FH-5.1.1
- Nutrition visit attendance FH-5.1.2
- Ability to recall nutrition goals FH-5.1.3
- Self-monitoring at agreed upon rate FH-5.1.4
- Self-management as agreed upon FH-5.1.5

#### Avoidance behavior (5.2)

- Avoidance FH-5.2.1
- Restrictive eating FH-5.2.2
- Cause of avoidance behavior FH-5.2.3

**Assessment & Monitoring & Evaluation**

## **APPENDIX 5. Focus on Nutrition Care Process: Nutrition Assessment—cont'd**

## **Nutrition Assessment and Monitoring and Evaluation Terminology, cont'd**

<b>Bingeing and purging behavior (5.3)</b>	<input type="checkbox"/> Binge eating behavior	FH-5.3.1	<input type="checkbox"/> Mini Mental State Examination Score	FH-7.2.8	<b>Gastrointestinal profile (1.4)</b>	<input type="checkbox"/> Alkaline phosphatase	BD-1.4.1

## APPENDIX 6. Focus on Nutrition Care Process: Nutrition Diagnosis

**Step 2. Nutrition diagnosis** is designed to identify and describe a specific nutrition problem that can be resolved or improved through intervention by a registered dietitian (RD). Unlike a medical diagnosis, a nutrition diagnosis often can be resolved. RDs use the data collected in the nutrition assessment to identify the patient's or client's nutrition diagnosis using standard terminology. The specific definition, possible causes, and common signs or symptoms are identified in this care process step. Nutrition diagnoses are organized into three categories:

Intake	Clinical	Behavioral-Environmental
Too much or too little of a food or nutrient compared with actual or estimated needs	Nutrition problems that relate to medical or physical conditions	Knowledge, attitudes, beliefs, physical environment, access to food, or food safety
The nutrition diagnosis is written as a problem, etiology, and sign and symptoms (PES) statement to describe the problem, its root cause, and the signs and symptoms (assessment data) that provide evidence for that nutrition diagnosis. The PES statement is “Nutrition problem label related to _____ as evidenced by _____.”		
(P) Problem (nutrition diagnosis)	(E) Etiology: Cause and Contributing Risk Factors	(S) Signs and Symptoms
Describes alterations in the patient's or client's nutrition status.	Linked to the nutrition diagnosis label by the words “related to.”	Data used to determine that the patient or client has the nutrition diagnosis specified; linked to the etiology by the words “as evidenced by.”

**APPENDIX 6.** Focus on Nutrition Care Process: Nutrition Diagnosis—cont'd**Nutrition Diagnostic Terminology****INTAKE**

**NI**  
Defined as "actual problems related to intake of energy, nutrients, fluids, bioactive substances through oral diet or nutrition support"

**Energy Balance (1)**

Defined as "actual or estimated changes in energy (kcal) balance"

- Unused NI-1.1
- Increased energy expenditure NI-1.2
- Unused NI-1.3
- Inadequate energy intake NI-1.4
- Excessive energy intake NI-1.5
- Predicted suboptimal energy intake NI-1.6
- Predicted excessive energy intake NI-1.7

**Oral or Nutrition Support Intake (2)**

Defined as "actual or estimated food and beverage intake from oral diet or nutrition support compared with patient goal"

- Inadequate oral intake NI-2.1
- Excessive oral intake NI-2.2
- Inadequate enteral nutrition infusion NI-2.3
- Excessive enteral nutrition infusion NI-2.4
- Less than optimal enteral nutrition NI-2.5
- Inadequate parenteral nutrition infusion NI-2.6
- Excessive parenteral nutrition infusion NI-2.7
- Less than optimal parenteral nutrition NI-2.8
- Limited food acceptance NI-2.9

**Fluid Intake (3)**

Defined as "actual or estimated fluid intake compared with patient goal"

- Inadequate fluid intake NI-3.1
- Excessive fluid intake NI-3.2

**Bioactive Substances (4)**

Defined as "actual or observed intake of bioactive substances, including single or multiple functional food components, ingredients, dietary supplements, alcohol"

- Inadequate bioactive substance intake NI-4.1
- Excessive bioactive substance intake NI-4.2
- Excessive alcohol intake NI-4.3

**Nutrient (5)**

Defined as "actual or estimated intake of specific nutrient groups or single nutrients as compared with desired levels"

- Increased nutrient needs NI-5.1  
(specify) \_\_\_\_\_
- Malnutrition NI-5.2
- Inadequate protein-energy intake NI-5.3
- Decreased nutrient needs NI-5.4  
(specify) \_\_\_\_\_
- Imbalance of nutrients NI-5.5

**Fat and Cholesterol (5.6)**

- Inadequate fat intake NI-5.6.1
- Excessive fat intake NI-5.6.2
- Inappropriate intake of fats NI-5.6.3  
(specify) \_\_\_\_\_

**Protein (5.7)**

- Inadequate protein intake NI-5.7.1
- Excessive protein intake NI-5.7.2
- Inappropriate intake of protein NI-5.7.3  
or amino acids (specify) \_\_\_\_\_

**Carbohydrate and Fiber (5.8)**

- Inadequate carbohydrate intake NI-5.8.1
- Excessive carbohydrate intake NI-5.8.2
- Inappropriate intake of types of carbohydrate (specify) \_\_\_\_\_ NI-5.8.3
- Inconsistent carbohydrate intake NI-5.8.4
- Inadequate fiber intake NI-5.8.5
- Excessive fiber intake NI-5.8.6

**Vitamin (5.9)**

- Inadequate vitamin intake NI-5.9.1  
(specify) \_\_\_\_\_
- A (1)  Riboflavin (7)
- C (2)  Niacin (8)
- D (3)  Folate (9)
- E (4)  B6 (10)
- K (5)  B12 (11)
- Thiamin (6)
- Other (specify) \_\_\_\_\_ (12)
- Excessive vitamin intake NI-5.9.2  
(specify) \_\_\_\_\_
- A (1)  Riboflavin (7)
- C (2)  Niacin (8)
- D (3)  Folate (9)
- E (4)  B6 (10)
- K (5)  B12 (11)
- Thiamin (6)
- Other (specify) \_\_\_\_\_ (12)

**Mineral (5.10)**

- Inadequate mineral intake NI-5.10.1  
(specify) \_\_\_\_\_
- Calcium (1)  Potassium (5)
- Chloride (2)  Phosphorus (6)
- Iron (3)  Sodium (7)
- Magnesium (4)  Zinc (8)
- Other (specify) \_\_\_\_\_ (9)
- Excessive mineral intake NI-5.10.2  
(specify) \_\_\_\_\_
- Calcium (1)  Potassium (5)
- Chloride (2)  Phosphorus (6)
- Iron (3)  Sodium (7)
- Magnesium (4)  Zinc (8)
- Other (specify) \_\_\_\_\_ (9)

**Multi-nutrient (5.11)**

- Predicted suboptimal nutrient intake NI-5.11.1
- Predicted excessive nutrient intake NI-5.11.2

**CLINICAL**

**NC**  
Defined as "nutritional findings/problems identified that relate to medical or physical conditions"

**Functional (1)**

Defined as "change in physical or mechanical functioning that interferes with or prevents desired nutritional consequences"

- Swallowing difficulty NC-1.1
- Biting/Chewing (masticatory) difficulty NC-1.2
- Breastfeeding difficulty NC-1.3
- Altered GI function NC-1.4

**Biochemical (2)**

Defined as "change in capacity to metabolize nutrients as a result of medications, surgery, or as indicated by altered lab values"

- Impaired nutrient utilization NC-2.1
- Altered nutrition-related laboratory values (specify) \_\_\_\_\_ NC-2.2
- Food-medication interaction NC-2.3
- Predicted food-medication interaction NC-2.4

**Weight (3)**

Defined as "chronic weight or changed weight status when compared with usual or desired body weight"

- Underweight NC-3.1
- Unintended weight loss NC-3.2
- Overweight/obesity NC-3.3
- Unintended weight gain NC-3.4

**BEHAVIORAL-****ENVIRONMENTAL****NB**

Defined as "nutritional findings/problems identified that relate to knowledge, attitudes/beliefs, physical environment, access to food, or food safety"

**Knowledge and Beliefs (1)**

Defined as "actual knowledge and beliefs as related, observed, or documented"

- Food- and nutrition-related knowledge deficit NB-1.1
- Harmful beliefs/attitudes about food- or nutrition-related topics (use with caution) NB-1.2
- Not ready for diet/lifestyle change NB-1.3
- Self-monitoring deficit NB-1.4
- Disordered eating pattern NB-1.5
- Limited adherence to nutrition-related recommendations NB-1.6
- Undesirable food choices NB-1.7

**Physical Activity and Function (2)**

Defined as "actual physical activity, self-care, and quality-of-life problems as reported, observed, or documented"

- Physical inactivity NB-2.1
- Excessive physical activity NB-2.2
- Inability or lack of desire to manage self-care NB-2.3
- Impaired ability to prepare foods/meals NB-2.4
- Poor nutrition quality of life NB-2.5
- Self-feeding difficulty NB-2.6

**Food Safety and Access (3)**

Defined as "actual problems with food safety or access to food, water, or nutrition-related supplies"

- Intake of unsafe food NB-3.1
- Limited access to food or water NB-3.2
- Limited access to nutrition-related supplies NB-3.3

Diagnosis

## APPENDIX 7. Focus on Nutrition Care Process: Nutrition Intervention

**Step 3. Nutrition interventions** are designed for the registered dietitian and team members to resolve or improve the identified nutrition diagnosis by planning and implementing appropriately tailored actions. Selection of a nutrition intervention is related to the **cause** of the nutrition problem. Intervention strategies are purposefully selected to change nutritional intake, nutrition-related knowledge or behavior, risk factors, environmental conditions, or access to supportive care and services. Intervention goals provide the basis for monitoring progress and measuring outcomes. Interventions are organized into four categories:

Food and Nutrient Delivery	Nutrition Education	Nutrition Counseling	Coordination of Nutrition Care
An individualized approach for food and nutrient provision, including meals and snacks, enteral and parenteral feeding, and supplements	A formal process to instruct or train a patient or client in a skill or to impart knowledge to help them voluntarily manage or modify food choices and eating behavior to maintain or improve health	A supportive process, characterized by a collaborative counselor-patient relationship, to set priorities, establish goals, and create individualized action plans that acknowledge and foster responsibility for self-care to treat an existing condition and promote health	Consultation with, referral to, or coordination of nutrition care with other health care providers, institutions, or agencies that can assist in treating or managing nutrition-related problems
<b>The two distinct and interrelated processes of intervention include:</b>			
Planning: Prioritizing nutrition diagnoses; consulting the American Dietetic Association's medical nutrition therapy evidence-based guides and other practice guides; determining patient-focused expected outcomes for each nutrition diagnosis; conferring with patient or client and caregivers; defining an intervention plan and strategies; defining time and frequency of care; identifying resources needed.			
Implementation: Communicating the nutrition care plan; carrying out the plan; collecting data, documenting, and modifying the plan based on goals and progress.			

**APPENDIX 7. Focus on Nutrition Care Process: Nutrition Intervention—cont'd****Nutrition Intervention Terminology****Nutrition Prescription**

The patient/client's individualized recommended dietary intake of energy and/or selected foods or nutrients based on current reference standards and dietary guidelines and the patient/client's health condition and nutrition diagnosis (*specify*).

  - Magnesium (4)         Zinc (8)
  - Other (specify) \_\_\_\_\_ (9)

**Bioactive Substance Management (3.3)**

*Addition or change in provision of bioactive substances.*

- Plant sterol and stanol esters ND-3.3.1
- Soy protein ND-3.3.2
- Psyllium and β-glucan ND-3.3.3
- Food additives ND-3.3.4
- Other (specify) \_\_\_\_\_ ND-3.3.5

**Feeding Assistance (4)**

*Accommodation or assistance in eating.*

- Adaptive equipment ND-4.1
- Feeding position ND-4.2
- Meal set-up ND-4.3
- Mouth care ND-4.4
- Other (specify) \_\_\_\_\_ ND-4.5

**Feeding Environment (5)**

*Adjustment of the factors where food is served that impact food consumption.*

- Lighting ND-5.1
- Odors ND-5.2
- Distractions ND-5.3
- Table height ND-5.4
- Table service/set up ND-5.5
- Room temperature ND-5.6
- Other (specify) \_\_\_\_\_ ND-5.7

**Nutrition-Related Medication Management (6)**

*Modification of a medication or herbal to optimize patient/client nutritional or health status.*

- Medications ND-6.1  
(specify prescription or OTC) \_\_\_\_\_
- Herbal/complementary products ND-6.2  
(specify) \_\_\_\_\_

**NUTRITION EDUCATION****NUTRITION COUNSELING****C****Theoretical Basis/Approach (1)**

*The theories or models used to design and implement an intervention.*

- Cognitive-Behavioral Theory C-1.1
- Health Belief Model C-1.2
- Social Learning Theory C-1.3
- Transtheoretical Model/Stages of Change C-1.4
- Other (specify) \_\_\_\_\_ C-1.5

**Strategies (2)**

*Selectively applied evidence-based methods or plans of action designed to achieve a particular goal.*

- Motivational interviewing C-2.1
- Goal setting C-2.2
- Self-monitoring C-2.3
- Problem solving C-2.4
- Social support C-2.5
- Stress management C-2.6
- Stimulus control C-2.7
- Cognitive restructuring C-2.8
- Relapse prevention C-2.9
- Rewards/contingency management C-2.10
- Other (specify) \_\_\_\_\_ C-2.11

**COORDINATION OF NUTRITION CARE****RC****Coordination of Other Care During Nutrition Care (1)**

*Facilitating services with other professionals, institutions, or agencies during nutrition care.*

- Team meeting RC-1.1
- Referral to RD with different expertise RC-1.2
- Collaboration/referral to other providers RC-1.3
- Referral to community agencies/programs (specify) \_\_\_\_\_ RC-1.4

**Discharge and Transfer of Nutrition Care to New Setting or Provider (2)**

*Discharge planning and transfer of nutrition care from one level or location of care to another.*

- Collaboration/referral to other providers RC-2.1
- Referral to community agencies/programs (specify) \_\_\_\_\_ RC-2.2

## APPENDIX 8. Focus on Nutrition Care Process: Nutrition Monitoring and Evaluation

**Step 4. Nutrition monitoring and evaluation** is the step designed to determine the amount of progress made and whether goals are being met. Nutrition monitoring and evaluation tracks patient or client outcomes relevant to the nutrition diagnosis and intervention plans and goals. Nutrition care outcomes—the desired results of nutrition care—have been defined, and specific indicators that can be measured and with reference standards or norms have been identified. The aim is to promote uniformity in assessing the effectiveness of nutrition intervention.

### What to Measure

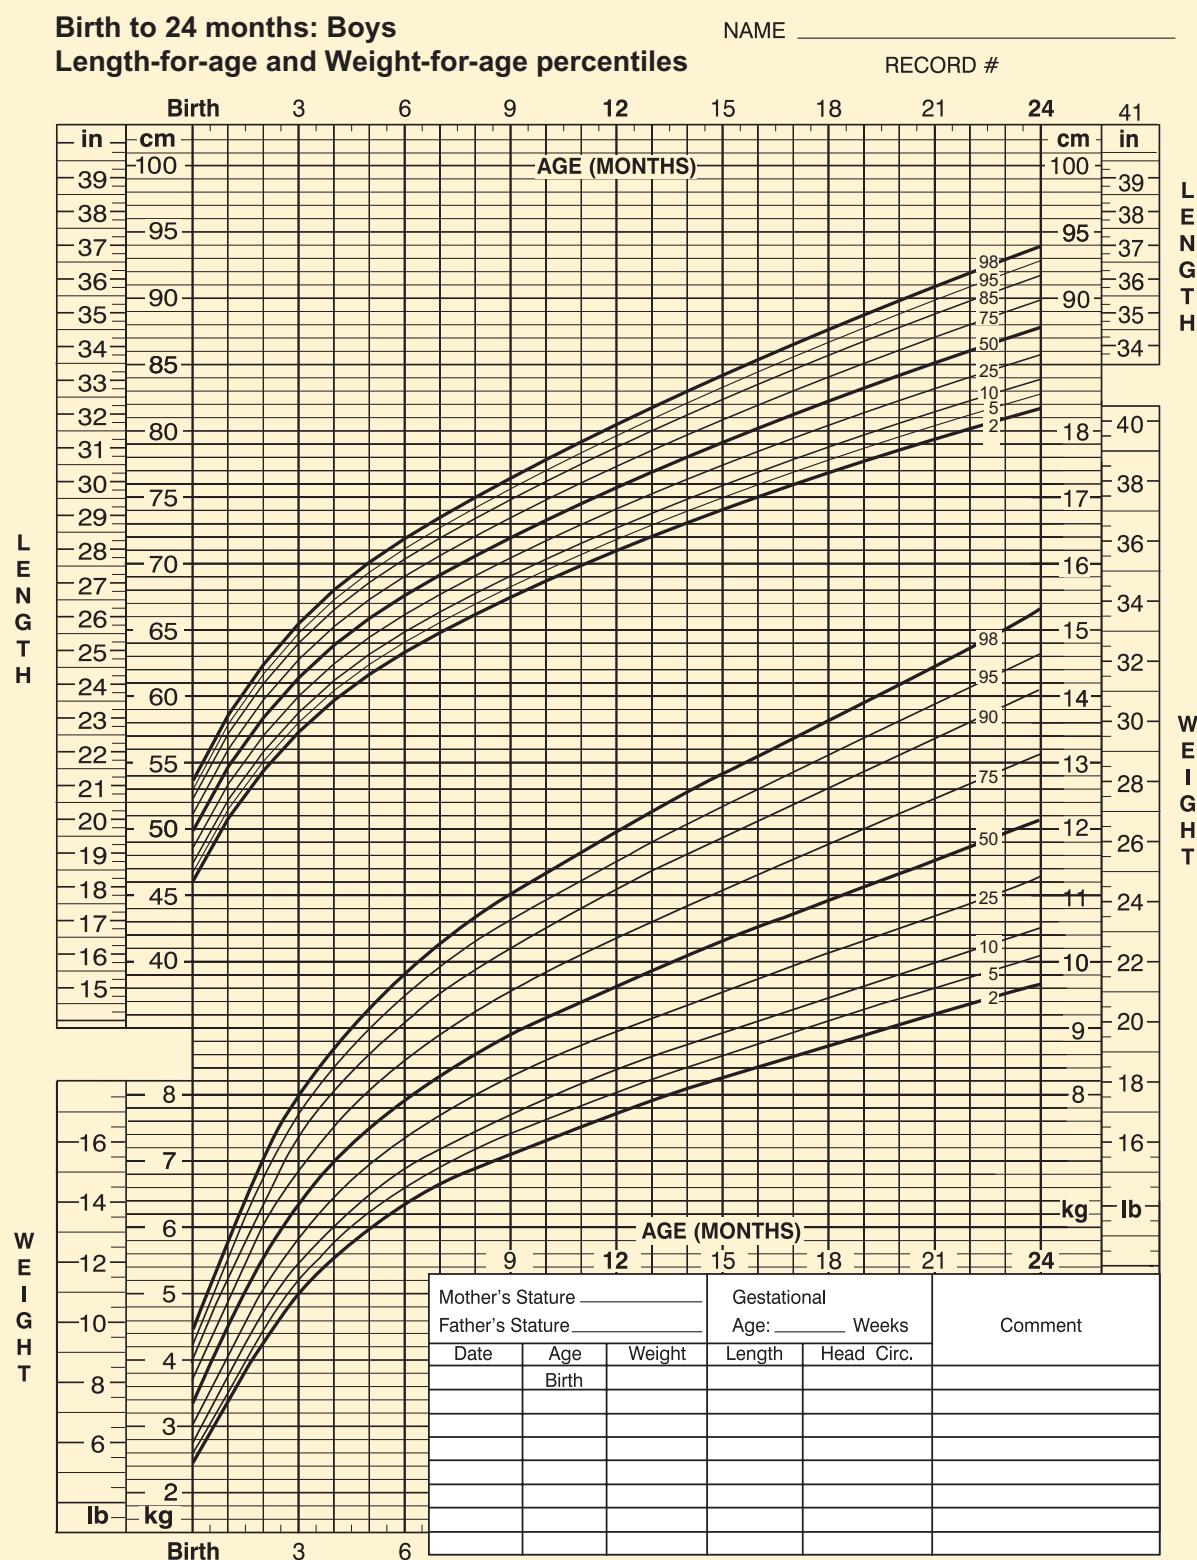

Selection of the appropriate nutrition care indicators is determined by the nutrition diagnosis, its causes and signs or symptoms, and the nutrition intervention used. The medical diagnosis and health care outcome goals and quality management goals for nutrition also influence which nutrition care outcome indicators are chosen. Other factors such as practice setting, patient or client population, and disease state and severity also affect the indicator selection. Outcomes for nutrition monitoring and evaluation are organized into four categories.

Food/Nutrition-Related History Outcomes	Anthropometric Measurement Outcomes	Biochemical Data, Medical Tests, and Procedure Outcomes	Nutrition-Focused Physical Finding Outcomes
Patient's or client's food and nutrient intake	Patient's or client's anthropometric, biochemical, and physical examination parameters	Patient's or client's lab data (e.g., electrolytes, glucose) and tests (e.g., gastric emptying time, resting metabolic rate)	Patient's or client's physical appearance, muscle and fat wasting, swallow function, appetite, and affect

**Monitor, Measure, and Evaluate:** Monitor the patient's or client's progress: determine whether the nutrition intervention is being implemented and provide evidence that the nutrition intervention is or is not changing the client's behavior or status. Measure the outcomes by selecting the appropriate nutrition care outcome indicators. Evaluate and compare the patient's current findings or indicator with previous status, nutrition intervention goals, and reference standards (i.e., criteria). See Appendix 5 for terms used in monitoring and evaluation.

## APPENDIX 17. Tanner Stages of Adolescent Development for Girls

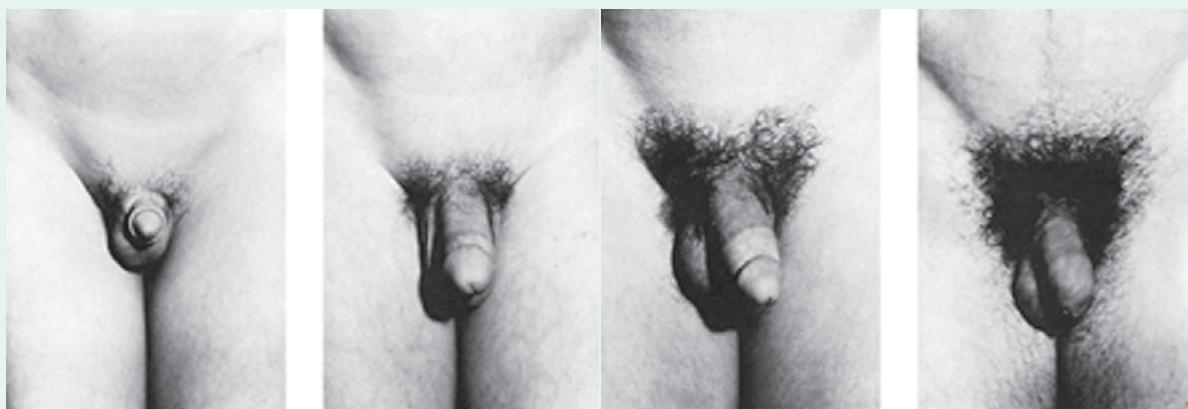

Chronologic age is not always the best way to assess adolescent growth because of individual variations in beginning and completing the growth sequence. A more useful way of describing pubertal development, and thus the varying needs for nutrients throughout adolescence, is to divide growth into stages of breast and pubic hair development in girls. These are termed the *Tanner Stages of Adolescent Development*. Nutritional requirements vary, depending on the stage of development.

From Mahan LK, Rees JM: Nutrition in adolescence, St Louis, 1984, Mosby.

## APPENDIX 18. Tanner Stages of Adolescent Development for Boys

Chronologic age is not always the best way to assess adolescent growth because of individual variations in beginning and completing the growth sequence. A more useful way of describing pubertal development, and thus the varying needs for nutrients throughout adolescence, is to divide growth into stages of pubic hair and penis and testicle development in boys. These are termed the *Tanner Stages of Adolescent Development*. Nutritional requirements vary, depending on the stage of development.

From Mahan LK, Rees JM: Nutrition in adolescence, St. Louis, 1984, Mosby.

## APPENDIX 19. Direct Methods for Measuring Height and Weight

### Height

1. Height should be measured without shoes.
2. The individual's feet should be together, with the heels against the wall or measuring board.
3. The individual should stand erect, neither slumped nor stretching, looking straight ahead, without tipping the head up or down. The top of the ear and outer corner of the eye should be in a line parallel to the floor (the "Frankfort plane").
4. A horizontal bar, a rectangular block of wood, or the top of the stadiometer should be lowered to rest flat on the top of the head.
5. Height should be read to the nearest  $\frac{1}{4}$  inch or 0.5 cm.

### Weight

1. Use a beam balance scale, not a spring scale, whenever possible.
2. Periodically calibrate the scale for accuracy, using known weights.
3. Weigh the subject in light clothing without shoes.
4. Record weight to the nearest  $\frac{1}{2}$  lb or 0.2 kg for adults and  $\frac{1}{4}$  lb or 0.1 kg for infants. Measurements above the 90th percentile or below the 10th percentile warrant further evaluation.

## APPENDIX 20. Indirect Methods for Measuring Height

### Measuring Arm Span

#### Steps:

1. The arms are extended straight out to the sides at a 90-degree angle from the body.
2. The distance from the longest fingertip of one hand to the longest finger of the other hand is measured.

### Adult Recumbent

#### Steps:

1. Stand on right side of the body.
2. Align body so that the lower extremities, trunk, shoulders, and head are straight.
3. Place a mark at the top of the sheet in line with the crown of the head and one at the bottom of the sheet in line with the base of the heels.
4. Measure length between marks with measuring tape.

### Knee Height

Knee height measurement is highly correlated with upright height. It is useful in those who cannot stand and in those who may have curvatures of the spine.

#### Steps:

1. Use the left leg for measurements.
2. Bend the left knee and the left ankle to 90-degree angles. A triangle may be used if available.
3. Using knee height calipers, open the caliper and place the fixed part under the heel. Place the sliding blade down against the thigh (approximately 2 inches behind the patella).
4. Measure from the heel to the anterior surface of the thigh, using a cloth measuring tape.
5. Obtain the measurement and convert it to centimeters by multiplying by 2.54.
6. Formulas to use to calculate estimated height from knee height:

$$\text{Men (height in centimeters)} = 64.19 - (0.04 \times \text{Age}) + (2.02 \times \text{Knee height in centimeters})$$

$$\text{Women (height in centimeters)} = 84.8 - (0.24 \times \text{Age}) + (1.83 \times \text{Knee height in centimeters})$$

### Predicting Stature From Knee Height: Recommended Equations for Predicting Stature from Knee Height in Adults (18 to 60 years) and Children (6 to 18 years)

Group	Equations
White men	Stature = 71.85 + (1.88 knee height) $R^2 = 0.65$ ; RMSE = 3.97; SEI = 3.97 cm; CV = 2.28
Black men	Stature = 73.42 + (1.79 knee height) $R^2 = 0.69$ ; RMSE = 3.60; SEI = 3.60 cm; CV = 2.08
White women	Stature = 70.25 + (1.87 knee height) - (0.06 age) $R^2 = 0.66$ ; RMSE = 3.60; SEI = 3.60 cm; CV = 2.23
Black women	Stature = 68.10 + (1.86 knee height) - (0.06 age) $R^2 = 0.69$ ; RMSE = 3.80; SEI = 3.80 cm; CV = 2.36
White boys	Stature = 40.54 + (2.22 knee height) $R^2 = 0.96$ ; RMSE = 4.16; SEI = 4.21 cm; CV = 2.79
Black boys	Stature = 39.60 + (2.18 knee height) $R^2 = 0.95$ ; RMSE = 4.44; SEI = 4.58 cm; CV = 2.99
White girls	Stature = 43.21 + (2.15 knee height) $R^2 = 0.95$ ; RMSE = 3.84; SEI = 3.90 cm; CV = 2.63
Black girls	Stature = 46.59 + (2.02 knee height) $R^2 = 0.94$ ; RMSE = 4.25; SEI = 4.39 cm; CV = 2.91

Data from Chumlea WC et al: Nutritional assessment of the elderly through anthropometry, Columbus, OH, 1984, Ross Laboratories.

CV, Coefficient of variation; RMSE, root mean square error; SEI, standard error for an individual.

## APPENDIX 21. Determination of Frame Size

**Method 1:** Height is recorded without shoes. Wrist circumference is measured just distal to the styloid process at the wrist crease on the right arm, using a tape measure. The following formula is used (From Grant JP: Handbook of total parenteral nutrition, Philadelphia, 1980, Saunders):

$$r = \frac{\text{Height (cm)}}{\text{Wrist circumference (cm)}}$$

Frame size can be determined as follows:

Males	Females
r >10.4 small	r >11.0 small
r = 9.6-10.4 medium	r = 10.1-11.0 medium
r < 9.6 large	r <10.1 large

**Method 2:** The patient's right arm is extended forward perpendicular to the body, with the arm bent so the angle at the elbow forms 90 degrees with the fingers pointing up and the palm turned away from the body. The greatest breadth across the elbow joint is measured with a sliding caliper along the axis of the upper arm on the two prominent bones on either side of the elbow. This is recorded as the elbow breadth. The following tables give the elbow breadth measurements for medium-framed men and women of various heights (from Metropolitan Life Insurance Co., 1983). Measurements lower than those listed indicate a small frame size; higher measurements indicate a large frame size.

Men		Women	
Height in 1" Heels	Elbow Breadth (inches)	Height in 1" Heels	Elbow Breadth (inches)
5'2"-5'3"	2½-2¾	4'10"-4'11"	2¼-2½
5'4"-5'7"	2¾-2½	5'0"-5'3"	2¼-2½
5'8"-5'11"	2¾-3	5'4"-5'7"	2¾-2½
6'0"-6'3"	2¾-3½	5'8"5'11"	2¾-2½
6'4"	2¾-3½	6'0"	

## APPENDIX 22. Adjustment of Desirable Body Weight for Amputees

The percentages listed here are estimates because body proportions vary in individuals. Use of these percentages provides an approximation of desirable body weight, which is more accurate than a comparison with the standards for normal adults. Ideal body weight (IBW) must be adjusted downward to compensate for missing limbs or paralysis. It is estimated that 5% to 10% should be subtracted from IBW for a paraplegic and from 10% to 15% subtracted for a tetraplegic (quadriplegic.)

### Adjustment of Ideal Body Weight for Amputees

Body Segment	Average % of Total Weight
Lower arm and hand	2.3
Trunk without extremities	50.0
Entire arm	5.0
Hand	0.7
Entire lower leg	16.0
Below knee including foot	5.9
Foot	1.5

Data from Brunnstrom S: *Clinical kinesiology*, Philadelphia, 1972, FA Davis.

$$\text{Estimated IBW} = \frac{100 - \% \text{ amputation}}{100} \times \text{IBW for original height}$$

To use this information, determine the patient's approximate height before the amputation. Span measurement is a rough estimate of height at maturity and is calculated as follows: with the upper extremities, including the hands, fully extended and parallel to the ground, measure the distance between the tip of one middle finger and the tip of the other middle finger. Use this height or actual measurement to calculate the desirable body weight for the normal body size; then adjust the figures according to the type of amputation performed.

Example: To determine the desirable body weight for a 5'10" male with a below-the-knee amputation:

- Calculate desirable body weight for a 5'10" male: 166 lb
- Subtract weight of amputated limb (6%) =  $166 \times 0.06$ :  $\underline{- 9.96}$  (approx. 10 lb)
- Desirable weight of a 5'10" male with a below-knee amputation: 156 lb

From North Carolina Dietetic Association: Nutrition care manual, 2011, Raleigh, NC, The Association.

From Durnin JVGA, Wormersley J: Body fat assessed from total body density and its estimation from skinfold thickness: measurements on 481 men and women ages 16-72 years, Br J Nutr 32:77, 1974.

\*Measurements made on the right side of the body, using biceps, triceps, subscapular, and suprailiac skinfolds.

## APPENDIX 25. Arm Anthropometry for Children

From Gurney JM, Jelliffe DB: Arm anthropometry in nutritional assessment: nomogram for rapid calculation of muscle circumference and cross-sectional muscle fat areas, Am J Clin Nutr 26:913, 1973.

**APPENDIX 26.** Arm Anthropometry for Adults

To obtain muscle circumference:

1. Lay ruler between value of arm circumference and fatfold.
2. Read off muscle circumference on middle line.

To obtain tissue areas:

1. The arm area and muscle area are alongside their respective circumferences.
2. Fat area = arm area – muscle area

From Gurney JM, Jelliffe DB: Arm anthropometry in nutritional assessment: nomogram for rapid calculation of muscle circumference and cross-sectional muscle fat areas, Am J Clin Nutr 26:913, 1973.

## APPENDIX 27. Recommendations for Clinical Application of Bioelectrical Impedance Analysis

Instruments, Material	Definition, Comments	Recommendations
Stadiometer Scale	Calibrated to 0.5 cm Calibrated to 0.1 kg	Use tape measure for subjects who are unable to stand and for knee height or arm span. Regularly cross-calibrate with other scales.
<b>Subjects</b>		
Height and weight	Measure height (0.5 cm) and weight (0.1 kg) at time of BIA measurement.	Self-reported height and weight not valid.
Food, drink, alcohol	Fasting, no alcohol for >8 h recommended	Shorter periods of fasting may be acceptable for clinical practice (vs. research).
Bladder voided Physical exercise Timing		Subject has voided before measurement. No exercise for >8 h. For longitudinal follow-up, perform measurement at the same time of day; note menstrual cycle.
Skin condition	Temperature Integrity Cleaning	Record ambient temperature. No skin lesions at site of electrodes; change site of electrodes. Clean with alcohol.
Electrode position	Note body site of measurement; distance between electrodes.	Always measure same body side. Minimum of 5 cm between electrodes; if needed, move proximal electrode.
Limb position	Abduction of limbs	Separate arms from trunk by approximately 30 degrees; separate legs by approximately 45 degrees.
Body position	Supine, except for "scale" type BIA instruments	Ambulatory subjects supine for 5 to 10 min; for research protocol, standardize time that subjects are supine before measurement; note if subject is confined to bed (patients).
Environment	Electrical interference	Ensure noncontact with metal frame of bed; neutral environment (no strong electrical or magnetic fields).
Body shape	Note body abnormalities.	Note measurement validity (e.g., R or Xc outside of expected range for subject). Consider validity of measurement when interpreting results (e.g., abnormally low R suggests edema).
Ethnic group	Amputation	Measure nonaffected limb; not valid for research but permits determination of body compartment because measurement error is consistent.
<b>Disease Conditions</b>		
Cardiac insufficiency Liver failure	Edema interferes with measurement. Ascites and edema interfere with measurement accuracy.	Measure nonaffected side. Note abnormal condition. Limited validity exists in conditions of abnormal body compartment distribution.
Kidney failure	Edema and altered ion balance interfere with measurement.	
Abnormal serum electrolyte concentrations	Electrolyte concentration affects BIA measurement.	Use electricity-isolating material (e.g., towel) between arm and trunk and between thighs. Note race; use race-specific BIA equation, if applicable.
Hypothyroid	Pachyderma	
<b>Treatments</b>		
Intravenous and electrolyte infusions	Peripheral edema interferes with measurement.	Measure patient in stable condition. Consider segmental BIA measurement.
Drugs that affect water balance	Steroids, growth hormone, diuretics	Perform BIA when serum electrolytes are within normal range. Compare BIA results when serum electrolyte concentrations are similar.
Dialysis	Hemo-1 peritoneal dialysis	May invalidate measurement because of high skin resistance.
Ascites puncture Orthopedic prostheses and implants (metal)	Hip prosthesis, for example	Measurements are invalid if patient is abnormally hydrated.
Pacemakers, defibrillators	Implanted cardiac defibrillator	If patient is in stable condition, measurement should be taken at same time after medication administration. Use special protocols; standardize measurement procedure (i.e., measurement should be performed 20 to 30 minutes after dialysis). Use special protocols; standardize measurement procedure. Measure nonaffected body side; note prostheses and implants.

Reprinted from Kyle UG, Bosaeus I, et al. Bioelectrical impedance analysis—Part II: Utilization in clinical practice, Clin Nutr 23:1430, 2004.

BIA, Bioelectrical impedance analysis; HIV, human immunodeficiency virus; R, resistance; Xc, reactance.

**APPENDIX 28.** Physical Activity and Calories Expended per Hour

<b>Activity</b>	<b>Type</b>	<b>Body Weight</b>							
		(110 lb)	(130 lb)	(150 lb)	(170 lb)	(190 lb)	(210 lb)	(230 lb)	(250 lb)

## APPENDIX 29. Nutrition-Focused Physical Assessment

Kathleen A. Hammond, MS, RN, BSN, BSHE, RD, LD

System	Normal Findings	Physical Findings	Possible Nutrition and Metabolic Associations	Nonnutritional Examples
General survey	Weight for height appropriate, well-nourished, alert, and cooperative	Loss of weight, muscle mass and fat stores, skeletal muscle wasting (especially in quadriceps, and deltoids), subcutaneous fat loss (face, triceps, thighs, waist) or overall weight loss, growth retardation, sarcopenia (loss of lean body mass in older adults)	Protein-energy deficiency Decreased food intake	Endocrine disorders, osteogenic disorders, menopausal disorders secondary to estrogen depletion Sarcopenia related to decreased physical activity, increased cytokine (interleukin-6) and decreased levels of growth hormone and insulin-like growth factor
Skin	Pink, soft, moist turgor with instant recoil, smooth appearance	Excess fat stores  Poor or delayed wound healing, pressure ulcers Dry with fine lines and shedding, scaly (xerosis) Spinelike plaques around hair follicles on buttocks, thighs, or knees (follicular hyperkeratosis)  Pellagrous dermatitis (hyperpigmentation of skin exposed to sunlight) Pallor  Generalized dermatitis	Protein, vitamin C, or zinc deficiency Essential fat or vitamin A deficiency Vitamin A or essential fat deficiency  Niacin or tryptophan deficiency Iron or folic acid deficiency  Zinc, essential fatty acid deficiency	Environmental or hygiene factors  Thermal, sun, or chemical burns Addison's disease Skin pigmentation disorders, hemorrhage, low volume, low perfusion state Atopic dermatitis, contact dermatitis, allergic or medication rash, psoriasis, connective tissue disease  Jaundice Aging process Aspirin overdose, liver disease, or trauma COPD, heart disease, aortic stenosis
Nails	Smooth, translucent, slightly curved nail surface and firmly attached to nail bed; nail beds with brisk capillary refill	Yellow pigmentation Poor skin turgor Petechiae, ecchymoses Spoon-shaped (koilonychia)	Carotene excess Fluid loss Vitamin K or C deficiency Iron deficiency	Chemical effects Infection, chemical effects Beau's lines, grooves caused by trauma, coronary occlusion, skin disease, transient illness
Scalp	Pink, no lesions, tenderness; fontanelles without softening, bulging	Softening or craniotabes	Vitamin D deficiency	Hydrocephalus
Hair	Natural shine, consistency in color and quantity, fine to coarse texture	Open anterior fontanel (usually closes by ~18 months of age) Lack of shine and luster, thin, sparse Easily pluckable	Vitamin D deficiency  Protein, zinc, or linoleic acid deficiency  Protein deficiency	Hypothyroidism, chemotherapy, psoriasis, color treatment Hypothyroidism, chemotherapy, psoriasis, color treatment

Continued

**APPENDIX 29.** Nutrition-Focused Physical Assessment—cont'd

System	Normal Findings	Physical Findings	Possible Nutrition and Metabolic Associations	Nutritional Examples
Face	Skin warm, smooth, dry, soft, moist with instant recoil	Alternating bands of light and dark hair in young children (flag sign) “Corkscrew” hair Diffuse depigmentation, swollen	Protein deficiency Copper (Menkes disease) Protein deficiency	Chemically processed or bleached hair Chemical alteration Steroids and other medications
		Pallor Moon face Bilateral temporal wasting Pale conjunctiva	Iron, folate, or B <sub>12</sub> deficiency Protein, calorie Protein, calorie Iron, folate, or B <sub>12</sub> deficiency	Low-perfusion, low-volume states Cushing's disease Neuromuscular disorders Low output states
Eyes	Evenly distributed brows, lids, lashes; conjunctiva pink without discharge	Night blindness Dry, grayish, yellow or white foamy spots on whites of eyes (Bitot's spots)	Vitamin A deficiency Vitamin A deficiency	Pterygium, Gaucher's disease
	sclerae, without spots; cornea clear; skin without cracks or lesions	Dull, milky, or opaque cornea (corneal xerosis) Dull, dry, rough appearance to whites of eyes and inner lids (conjunctival xerosis) Softening of cornea (keratomalacia) Cracked and reddened corners of eyes (angular palpebitis) Scaly, greasy; with gray or yellowish material around nares (nasolabial seborrhea)	Vitamin A deficiency Vitamin A deficiency Vitamin A deficiency Riboflavin, niacin deficiency Riboflavin, niacin, pyridoxine deficiency	Chemical, environmental Infection, foreign objects
Nose	Uniform shape, septum slightly to left of midline, nares patent bilaterally, mucosa pink and moist, able to identify smells	Inflammation, redness of sinus tract, discharge, obstruction or polyps	Inflammation of skin membranes	Need to reconsider if placing nasoenteric feeding tube; evaluate for nonfood allergies
<b>Oral Cavity</b>				
Lips, mouth	Pink, symmetric, smooth intact	Bilateral cracks, redness of lips (angular stomatitis) Vertical cracks of lips (cheilosis)	Riboflavin, niacin, pyridoxine deficiency Riboflavin, niacin deficiency	Poor-fitting dentures, herpes, syphilis Acquired immune deficiency syndrome (Kaposi's sarcoma), environmental exposure
Tongue	Pink, moist, midline, symmetric with rough texture	Magenta (purplish-red color), inflammation of the tongue (glossitis)	Riboflavin deficiency, B <sub>6</sub> , niacin, folate, B <sub>12</sub> , B <sub>2</sub>	Crohn's Disease, uremia, Infectious disease state, antibiotics, malignancy, Irritants (excess tobacco, alcohol, spices), generalized skin disorder
		Smooth, slick, loss of papillae (atrophic filiform papillae) Beefy red color, atrophied taste buds, mucosa red and swollen Decreased taste (hypogeusia) Distorted taste (dygeusia)	Folate, niacin, riboflavin, iron, or B <sub>12</sub> deficiency Niacin, folate, riboflavin, iron, B <sub>12</sub> or pyridoxine deficiency Zinc deficiency	Crohn's disease, infection Cancer therapy, advanced age

Gums	Pink, moist without sponginess	Spongy, bleeding, receding	Vitamin C deficiency
Teeth	Repaired, no loose teeth; color may be various shades of white	Missing, poor repair, caries, loose White or brownish patches (mottled)	Excess sugar Excess fluoride Feeding route Ability to chew properly
Cranial nerves	Intact	Absent	Bulimia, cysts, tumors, hyperparathyroidism Cancer, allergy, cold infection
Gag reflex	Intact	Proper alignment, movement from side to side	
Jaw	Proper alignment, movement from side to side	Located anterior to earlobe, no enlargement	
Parotid gland	Enlarged thyroid	Bilateral enlargement	
Neck nodules	Trachea midline, freely movable without enlargement or nodules	Enlarged thyroid	
<b>Cardiopulmonary</b>			
Chest, lungs	Anterior and posterior thorax; adequate muscle and fat stores, respirations even and unlaborated, symmetric rise and fall of chest during inspiration and expiration, lung sounds clear	Somatic muscle- and fat-wasting; labored respirations; breath sounds such as crackles, rhonchi, and wheezing; evaluate for fluid status vs. tenacious secretions that may labor breathing and increase energy expenditure; also consider increased rate and depth, decreased rate and depth	Protein-energy deficiency Metabolic acidosis Metabolic alkalosis
Heart	Rhythm regular and rate within normal range; $S_1$ and $S_2$ heart sounds	Irregular rhythm	Potassium deficiency or excess calcium deficiency
			Magnesium deficiency or excess phosphorus deficiency
		Enlarged heart	Thiamin deficiency associated with anemia and beriberi
		Pitting edema	Retention of sodium chloride, which causes the body to retain water
			Edema-associated disease of heart, liver, kidneys
Vascular access devices intact	No swelling, redness, drainage	Purulent drainage, swelling, excessive redness	Fluid leaking into the interstitial tissue spaces
Abdomen	Soft, nondistended, symmetric, bilateral without masses, umbilicus in midline, no ascites, bowel sounds present and normoactive, tympanic on percussion; feeding device intact without redness, swelling	Generalized symmetric distention	Nutrition effects if device has to be removed Obesity
			Effects on protein, fluid, sodium concerns of feeding
		Protruding, everted umbilicus; tight glistening appearance (ascites)	Protein-calorie deficiency
		Scaphoid appearance	Nutrition effects in gastritis (normal if hunger pains)
		Increased bowel sounds	

Continued

## APPENDIX 29. Nutrition-Focused Physical Assessment—cont'd

System	Normal Findings	Physical Findings	Possible Nutrition and Metabolic Associations	Nonnutritional Examples
Kidney, ureter, bladder	Urine golden yellow (ranges from pale yellow to deep gold), clear without cloudiness, adequate output	High-pitched tinkling	Nutrition effects if intestinal fluid and air present, indicating early obstruction	
	Decreased output	Decreased bowel sounds	Nutrition effects if peritonitis or paralytic ileus present	
Musculoskeletal	Full range of motion without joint swelling or pain, adequate muscle strength	Inability to flex, extend, and rotate neck adequately	Interference with ability to feed or make hand-to-mouth contact	
	Urinary output	Decreased range of motion, swelling, impaired joint mobility of upper extremities; muscle wasting on arms, legs; skin folding on buttocks	Protein-calorie deficiency	
Neurologic	Alert, oriented, hand-to-mouth coordination; no weakness or tremors	Swollen, painful joints Enlargement of epiphyses at wrist, ankle, or knees Bowed legs Beading of ribs Pain in calves, thighs	Vitamin C deficiency Vitamins D or C deficiency Vitamin D deficiency, calcium deficiency Vitamin D deficiency, calcium deficiency Thiamin deficiency	Connective tissue disease Trauma, deformity, or congenital cause
		Decreased or absent mental alertness; inadequate or absent hand-to-mouth coordination	Interference with the ability to feed or make hand-to-mouth contact	Renal rickets, malabsorption Deep vein thrombosis, other neuropathy or other
		Psychomotor changes, confusion, peripheral neuropathy Tetany	Protein deficiency; thiamin, pyridoxine, vitamin B <sub>12</sub> deficiency Calcium, magnesium deficiency	Trauma, neurologic disease
		Cranial nerves intact: primary nutritionally focused ones include trigeminal, facial, glossopharyngeal, vagus, and hypoglossal Reflexes (biceps, brachioradialis patella, and Achilles common in examination), functioning within normal range of 2 <sup>++</sup>	Hypocalcemia Hypokalemia	Associated with metabolic diseases such as diabetes mellitus and hypothyroidism
		Hypoactive reflexes	Hypoactive Achilles, patellar reflex	Thiamin, vitamin B <sub>12</sub>
				Neurologic disorder

This chart is not intended to be a comprehensive list for all nutritional or metabolic deficiencies or nonnutrition examples.

## APPENDIX 30. Laboratory Values for Nutritional Assessment and Monitoring

Diana Noland, MPH, RD, CCN

### I. Principles of Nutritional Laboratory Testing

#### A. Purpose

Laboratory-based nutritional testing, used to estimate nutrient availability in biologic fluids and tissues, is critical for assessment of both clinical and subclinical nutrient deficiencies. Laboratory data are the only objective data used in nutrition assessment that are “controlled”—that is, the validity of the method of its measurement is checked each time a specimen is assayed by also assaying a sample with a known value. The known sample is called a *control*, and if the value obtained for the sample is outside the range of normal analytic variability, both the specimen and control are measured again. The nutrition professional can use laboratory data to support subjective data and clinical assessment findings. Furthermore, because numeric values do not themselves connote personal judgment, this kind of data can often be passed on to a patient or client without implicit or perceived blame.

#### B. Specimen Types

Ideally the specimen to be tested reflects the total body content of the nutrient to be assessed. However, often the best specimen is not readily available. The most common specimens for analysis are the following:

**Whole blood**—Must be collected with an anticoagulant if entire content of the blood is to be evaluated. The two common anticoagulants for whole blood analyses are ethylenediaminetetraacetic acid, a calcium chelator used in hematologic analyses, and heparin (maintains the blood in its most natural state).\*

**Blood cells**—Separated from anticoagulated whole blood for measurement of cellular analyte content.

**Plasma**—The uncoagulated fluid that bathes the formed elements (blood cells).

**Serum**—The fluid that remains after whole blood or plasma has coagulated. Coagulation proteins and related substances are missing or significantly reduced.

**Urine**—Contains a concentrate of excreted metabolites.

**Feces**—Important in nutritional analyses when nutrients are not absorbed and therefore are present in fecal material.

**Hair**—An easy-to-collect tissue; usually a poor indicator of actual body levels.

**Other tissues**—Buccal cells and solid organ biopsy specimens are rarely used in nutrition laboratory assessment.

#### C. Interpretation of Laboratory Data

As with all data, nutrition data may be quantitative (e.g., how much, how often, how fast), semiquantitative (e.g., many, most, few, a lot, usually, majority, several), or qualitative (e.g., color, shape, species). The advantage of quantitative data is that they are less ambiguous or more objective than other types of observations. Although objective laboratory data are extremely important resources in nutrition assessment, one should be extremely cautious about using a single isolated laboratory test value to make an assessment. One value is often misleading, especially when taken out of the context of an individual's habits, clinical status, and dietary and medical histories. The best data are obtained from analysis of changes in laboratory values. When monitoring patients for changes in nutrition test values, one must consider how much change is necessary to give confidence that a difference is significant. The change required for statistical significance has been called the *critical difference*. It is calculated from measurement of the variances calculated from repeated measurements of an analyte: (1) specimens that have been obtained, at several different times, from each of several healthy persons (intrasubject variation); and (2) separate samples from a large specimen pool (analytic variation).

The critical differences for some plasma proteins of nutritional significance are the following:<sup>†</sup>

Protein	Critical Difference
Albumin	8%
Prealbumin/transthyretin	32%

The statistical probability that two consecutive albumin measurements are statistically different requires that the concentration change by 8% or more. Therefore an albumin increase, for example, from 30 g/L to 32.4 g/L indicates that a statistically significant change has occurred. For prealbumin, an increase from 30 mg/dL to 39.6 mg/dL would be significant. There are two reasons for the large discrepancy in the critical differences for these three proteins. The major reason is that the albumin level is very stable in healthy persons, whereas prealbumin concentrations vary considerably. Also contributing to these differences is the fact that the currently available methods measure albumin more precisely than prealbumin. In practice, assessments are not based on the measurement of a single analyte at one point in time. Changes in laboratory tests may have biologic significance (e.g., patient's condition is improving) long before statistical significance is achieved. The changes in laboratory data may precede changes in other nutritional indices, but generally, although not always, the data available should point to the same conclusion.

#### D. Reference Ranges

To determine whether a particular laboratory value is abnormal, particularly when serial data are not available, the value is generally compared to a reference range. The reference range is constructed from a large number of test values (20 to >1000). The average value and the standard deviation for these data are determined, and the reference range is calculated from the mean  $\pm 2$  standard deviations. If the sample group is representative of the reference population, the reference range will include values that reflect those found in approximately 95% of the reference population. Approximately 2.5% of this normal population will have values greater than the upper end of the reference range, and 2.5% will have values less than the lower end. This means that one normal individual in 20 would have a value below or above the reference range.

Reference ranges can be made for different populations. For example, reference ranges based on gender, age, race, and so forth, can be developed.

In practice, the differences between populations are often ignored because the importance of small differences in a nutrient analyte is not usually significant. However, in the event of borderline values, the possible influence differences between the population of which the patient is a member and the reference population may need to be taken into account. Reference ranges often are determined by obtaining blood from personnel working in or near the clinical laboratory. This population is often skewed toward younger persons, has few minorities, and is overrepresented by women.

*Continued*

## APPENDIX 30. Laboratory Values for Nutritional Assessment and Monitoring—cont'd

### E. Units

Many types of units are used in reporting nutrient-dependent laboratory values. Two basic systems of units are in common use: the conventional system and the Système Internationale d'Unités (SI) system.<sup>‡</sup> The conventional system sometimes lacks convention; thus different laboratories adopt different units to report the same analyte. For example, the conventional report of an ionized calcium value could be 2.3 mEq/L, 46 mg/L or 4.6 mg/dL. However, in the SI system only 1.15 mmol/L is allowed.

### F. Nature of Nutritional Testing and Types of Tests

Typically laboratory tests are static assays (i.e., the concentration of an analyte is measured in a biologic fluid [e.g., a fasting blood specimen] at a point in time). Assessment of nutrient status made by this approach is often inaccurate or distorted. Some nutrients can be assessed by tests that are based on measurements that reflect the endogenous availability of a nutrient to a measurable biologic function (e.g., biochemical, tissue, or organ). Most often, functional assessment of nutrient status may be done by measurement of a biochemical marker (i.e., a normal or abnormal metabolite) of function. The results of this type of testing can be reliably considered to reflect the adequacy of a nutrient pool.

\*Samples obtained for blood coagulation tests are diluted with solutions containing sodium citrate (a calcium chelator). Because of the dilutional effect of the anticoagulant solutions, citrated samples are not suitable for measurement of the concentrations of analytes.

Sections of this appendix were written by Mary Litchford, RD, PhD, for the previous edition of this text.

## NEW DIRECTIONS

### Bioelectrical Impedance Analysis (BIA)—A New Functional Test?

Nutrition assessment is taking on a new level of specificity with the explosion of technology and discoveries of the pathophysiology of disease and functions of the human body. These breakthroughs assist in molecular level identification of nutrition status. Bioelectrical Impedance Analysis (BIA) has a credible history of use in research, but recently has found an increasing use as a clinical tool in nutrition assessment.

BIA estimates body composition and cellular activity by measuring the bulk electrical impedance of the body. The testing procedure involves application of conductors (electrodes) to a person's hand and foot, and sending a small alternating electric current through the body. The different electrical conductive properties of various body tissues (adipose, muscular and skeletal) affect the impedance measurement. An algorithm derived from statistical analysis of BIA measurements is used to calculate the various parameters that can be measured by this technique. Normal hydration is critical for results to be valid, with guidelines prior to testing: drink water (16-24 oz during 4 hours prior to test), and no alcohol (12 hours), food or caffeine drinks (4 hours), or exercise (12 hours) prior to test. Contraindications to BIA testing are pregnancy, or the presence of implants like pacemakers or defibrillators. Follow-up monitoring testing should attempt to be near the same time of day.

There are commercially available BIA devices that measure only body fat % and weight. But professional BIA instruments are available that provide reliable, more comprehensive data, and automatically calculate total body water,

intracellular & extracellular water, fat-free mass, percent body fat, phase angle, capacitance and body cell mass. They are very useful in being to track changes in an individual's progress over time.

The multiple parameters measured in a BIA test provide three categories of data:

1. *Anthropometric*: BMI, BMR, Body Fat %, and Lean Body Mass %. These measurements are used with weight management, monitoring wasting syndromes, and acute care formulation of dietary prescriptions. Weight/height/age/gender date must be entered to obtain these results.
2. *Cellular metabolism*: Phase angle (cell membrane fluidity/prognostic marker of mortality), Capacitance (electrical resistance cell membrane), Body Cell Mass (metabolically active cells). Using these three measurements provide an easy-to-use, non-invasive, and reproducible technique to evaluate changes in body composition and nutritional status. Phase angle (BIA) detects changes in tissue electrical properties and is hypothesized as a marker of malnutrition for investigating various diseases in the clinical setting. Lower phase angles suggest cell death or decreased cell integrity, while higher phase angles suggest large quantities of intact cell membranes (Selberg).
3. *Hydration*: Total Body Water (lb. & %), Intracellular water (lb. & %), Extracellular water (lb. & %) Examples for clinical use: general health management, wound care, prevention of pressure ulcers.

## APPENDIX 30. Laboratory Values for Nutritional Assessment and Monitoring—cont'd

### II. Clinical Chemistry Panels

#### A. Protein Status

Test	Principles	Interpretation	Reference Range	Limitations and Implications
Urea Urinary Nitrogen (UUN)	The protein pool (visceral and somatic) N is catabolized to urea; urine urea represents ~80% of N catabolized; requires accurate estimate of protein intake; thus usually used only for TPN or tube-feeding patients. Some N is excreted as non-urea N (e.g., ammonia and creatinine); 24-hour TUN reflects total protein catabolism, accounting for all sources of urinary N; as for UUN, requires accurate protein intake. Used primarily to accurately follow the protein catabolic response during disease and response to nutritional support.	UUN is compared with the actual N intake. Nitrogen Balance = Nitrogen intake (Protein g/day ÷ 6.25) – Nitrogen Losses (UUN (g) + 4) <sup>a</sup>	- = Catabolism 0 = Catabolism + = Anabolism (3-6 g/24 hr = optimal use range)	24 hour urine collection must be quantitative (complete); UUN not appropriate in renal insufficiency; does not account for wound leakage, cell losses, or diarrhea; inaccurate in metabolically stressed patients. Urine 24 hour collection must be quantitative (complete); TUN not appropriate in renal insufficiency; not done in many institutions; does not account for wound leakage, cell losses, or diarrhea. <sup>1</sup>
Total Urinary Nitrogen (TUN)	Some N is excreted as non-urea N (e.g., ammonia and creatinine); 24-hour TUN reflects total protein catabolism, accounting for all sources of urinary N; as for UUN, requires accurate protein intake. Used primarily to accurately follow the protein catabolic response during disease and response to nutritional support.	TUN is compared with the actual N intake; Nitrogen Balance = Nitrogen intake (Protein g/day ÷ 6.25) – Nitrogen Losses (TUN (g) + 2) <sup>b</sup>	- = Catabolism 0 = Catabolism + = Anabolism (3-6 g/24 hr = optimal use range)	Urea lost in dialysis must be accounted for in calculating urea nitrogen appearance. Dietary protein intake hard to estimate.
Urea Kinetic Modeling (UKM)	Formulas used to estimate nPCR from changes in BUN concentration in patients with impaired renal function.	Urinary urea (KrU) and BUN levels (urea generation rate—GU) are used to determine nPCR; 1- to 3-day diet intake compared with nPCR.	In protein balance, nPRC = protein intake (g/kg/day)	Urea lost in dialysis must be accounted for in calculating urea nitrogen appearance. Dietary protein intake hard to estimate.
<b>Visceral Proteins</b>				
Total protein (TP)	Protein concentration in serum is easily measured colorimetrically; largely reflects albumin (~50% of TP) and globulin (~50%).	TP levels parallel clinical signs of malnutrition if significant inflammatory condition not present; plasma TP is 0.4 g/dL greater than serum TP.	6.4-8.3 g/dL (64-83 g/L)	Total protein measurements can reflect nutritional status and may be used to screen for kidney and liver disease; does not reflect protein status during inflammatory (acute-phase) response; monitor other inflammatory markers when evaluating TP.
Albumin (ALB)	Easily and quickly measured colorimetrically; large body pool (3-5 g/kg body weight), ~60% is outside the plasma in the extravascular pool; long half-life of 3 weeks.	Decreased levels can occur following short-term protein and energy deficiency or protein exudates such as in severe burns; often associated with other deficiencies (i.e., zinc, iron, and vitamin A) reflecting the ALB transport function of many small molecules.	3.5-5 g/dL (35-50 g/L)	Stable half life ~3 weeks. Preserved in the presence of starvation (marasmus). Significance confounded by being a negative phase reactant, liver disease, protein-losing enteropathy, nephrotic syndrome, pregnancy, oral contraceptive use, strenuous exercise, and hemodilution. Hepatic proteins are indicators of morbidity and mortality: help identify patients who are at increased nutritional risk because of trauma or illness. <sup>1</sup>
Globulin (GLOB)	Large body pool (3-5 g/kg body weight), ~35% is outside the plasma in the extravascular pool; long half-life averages 23 days, but varies with particular globulins.	Globulin proteins include enzymes and carriers that transport proteins including antibodies that primarily assist in immune function and fight infection.	2.3-3.4 g/dL (23-34 g/L)	Significance confounded by acute stress reaction, infection, inflammatory conditions. <sup>1</sup>

A/G Ratio	Calculated from ALB and GLOB values by direct measurement of TP and ALB.	It represents the relative amounts of ALB and GLOB	A/G Ratio 1:1 - normal <1:1 - disease state
Normalized Protein Catabolic Rate (nPCR)	nPCR is determined by measuring the intradialytic appearance of urea in body fluids plus any urea lost in the urine in patients with residual renal function. $\text{nPCR} = 0.22 + (0.036 \times \text{*intradialytic rise in BUN} \times 24) / (\text{intradialytic interval})$ (also called: Protein Nitrogen Appearance rate (PNA) (g/day) = $13 + 7.31 \text{ UNA (mmol/day)} / [\text{UNA (mmol/L)} + \text{Vu (ml)} + \text{Cu (mmol/L)}]$ ) The iron bound globulin protein that responds to the need for iron. Can be calculated from TIBC and serum iron; half-life ~9 days. See Chapter 8	Useful in assessing Dietary Protein Intake (DPI) in patients who are in a steady state on hemodialysis, as a means toward determining adequate nutrition status.	nPCR considered superior to sAlb for monitoring nutrition protein status due to sAlb influence by processes other than nutrition status. <sup>2</sup> During hemodialysis the PCR can also reflect inadequate dialysis. For CAPD patients the nPCR value has not been consistently predictive of outcome. <sup>3</sup>
Transferrin (Tf or TfN)	Tf increased with low iron stores, and prevents build up of highly toxic excess unbound iron in circulation. In iron overload states Tf levels decrease. Because B6 is required for iron to bind to Hgb, B6 deficiency promotes ↑ Tf from the ↑ circulating iron that binds to Tf; smaller extravascular pool than albumin.	Adult male: 215-365 mg/dL (2.15-3.65 g/L) Adult female: 250-380 mg/dL (2.50-3.80 g/L) Newborn: 130-275 mg/dL (1.3-2.75 g/L) Child: 203-360 mg/dL (2.03-3.6 g/L) Pregnancy and estrogen HRT associated with ↑ Tf.	Lead can biologically mimic and displace iron thus releasing Fe into circulation and ↑ Tf. Tf is a negative acute phase reactant diminished in chronic illness and hypoproteinemia.
Transferrin Saturation (Tf-sat or TSAT)	Tf-sat (%) = Serum iron level/TIBC x 100% More sensitive protein-energy balance indicator than ALB or transferrin even during inflammatory conditions; responds rapidly to nutrition intervention; reportedly more sensitive to energy intake than to protein intake. Zinc deficiency reduces PAB levels.	M: 20%-50% F: 15%-50% Chronic illness: normal Tf-sat%. Late pregnancy: low Tf-sat%. 15-36 mg/dL or 150-360 mg/L (1.5-3.6 g/L) Malnutrition: <8 mg/dL (<0.8 g/L or <80 mg/L)	Increased Tf-sat when low vitamin B <sub>6</sub> as in aplastic anemia.
PreAlbumin (PAB)/ Transthyretin (TR)	Transports T <sub>4</sub> and acts as a carrier for retinol-binding protein; PAB also called <i>thyroxin-binding protein</i> ; half-life 2 days.	More sensitive protein-energy balance indicator than ALB or transferrin even during inflammatory conditions; responds rapidly to nutrition intervention; reportedly more sensitive to protein intake than to energy intake.	Very sensitive to stress response, also ↓ in liver disease, protein-losing enteropathy, nephrotic syndrome, vitamin A and zinc deficiencies, and hemodilution; increased in chronic renal disease, regardless of PEM status. Reduced levels seen in hypopituitarism, hypothyroidism, liver disease, and with estrogen use.
Retinol-binding protein (RBP)	Transport retinol; because of low molecular weight, RBP is filtered by glomerulus and catabolized by the kidney tubule; half-life = 12 hours	More sensitive protein-energy balance indicator than ALB or PAB; responds rapidly to nutritional intervention; reportedly more sensitive to protein intake than to energy intake.	2.6-7.6 mg/dL (1.43-2.86 mmol/L) Adult: 42-110 ng/mL Children age 0-19: can vary with age and gender
Insulin-like growth factor-1 (IGF-1) (Somatomedin C)	The peptide mediator of growth hormone activity produced by the liver; half-life of a few hours; much less sensitive to stress response than other proteins.	Elevated levels associated with elevated GH in acromegaly and neoplastic activity.	Tanner Stages (Appendices 17 & 18) used for references per age

Continued

## APPENDIX 30. Laboratory Values for Nutritional Assessment and Monitoring—cont'd

Test	Principles	Interpretation	Reference Range	Limitations and Implications
<b>B. Tests of Metabolic Indicators</b>				
Urine creatinine (U:Cr)	U:Cr concentration in fasting, first-void urine used to compare amino acid catabolism (BUN) with muscle mass (creatinine).	Urine concentration (mg/dL) U:Cr = Urine urea (mg/dL) + Urine creatinine (mg/dL). The U:Cr is used in comparing other markers like microalbumin, albumin, GFR ratios.	Risk Low Medium High	Ratio >12.0 6.0-12.0 <6.0
Hemoglobin A1C (HgbA1C)	Glycosylated hemoglobin; dependent on blood glucose level over life span of RBC (120 days); the more glucose the GHb is exposed, the greater the % HgbA1C.	Elevated levels associated with hyperinsulinemia related to metabolic syndrome; diagnosis of insulin-producing neoplasms; excess insulin associated with inflammatory conditions.	Non-diabetic adult/child: 4%-5.9% Controlled diabetes (DM): 4-7% Fair DM control: 7-8% Poor DM control: >8%	HbA1 measurement is a simple, rapid, and objective procedure. Home testing available.
Insulin, fasting	Pancreatic hormone signaling cell membrane insulin receptors to initiate glucose transport into cell; Test fasting 7 hours, or 1 or 2 hours post prandial; usually ordered with blood glucose test.	Adult values: Fasting 6-27 µIU/mL 1 or 2 hour PP: see lab reference	Good test and retest reliability, and covariance is stable over time. <sup>8</sup> Insulin antibodies may invalidate the test.	
Triglycerides (TG)	TG molecule of glycerol with three fatty acids; Blood test fasting 12-14 hours.	TG increase following a meal, sugar or alcohol. Accurate CVD risk with calculation of LDL/VLDL; TG >1000 associated with pancreatitis.	Age adjusted normal: <150 mg/dL (<1.7 mmol/L) Borderline High: 150-199 mg/dL (1.8 to 2.2 mmol/L) High: 200-499 mg/dL (2.3 to 5.6 mmol/L)	Good test and retest reliability, and covariance is stable over time.
Low Density Lipoproteins (LDL-C)	12-14 hour fasting sample	LDL-C indicating cardiovascular risk.	Very high—500 mg/dL or above (5.7 mmol/L or above) Normal: 100-130 mg/dL If high risk CVD patient: <100 mg/dL If very high risk CVD patient: <70 mg/dL	Good test and retest reliability, and covariance is stable over time.
Fibrinogen	Acute-phase reactant protein essential to blood-clotting mechanism/coagulation system.	Decreased fibrinogen related to prolonged PT and PTT; produced in liver; rises sharply during tissue inflammation or necrosis; association with CHD, stroke, myocardial infarction and peripheral arterial disease.	200-400 mg/dL If <100 mg/dL, increased risk of bleeding. Should be monitored in conjunction with blood platelet levels involved with coagulation status.	Good test and retest reliability, and covariance is stable over time; diets rich in Omega 3/6 fatty acids reduce fibrinogen blood levels.
C-Reactive Protein (hs-CRP)	A nonspecific acute phase reactant; short half life 5-7 hr; CRP responds to inflammation in 6-10 hours. (also called CRP-ultra sensitivity and CRP-cardio)	A sensitive marker of bacterial disease and systemic inflammation; associated with periodontitis, trauma, cardiovascular disease, neoplastic proliferation and bacterial infections.	Low Risk for CVD = Less than 1.0 mg/L Intermediate Risk for CVD = 2.9 mg/L High Risk for CVD = Greater than 3.0 mg/L	Useful metabolic indicator for adults. <sup>9</sup> Acute-phase reactant; relates mostly to bacterial infection, central adiposity, trauma and neoplastic activity.

### C. Immune Dysregulation Tests

Allergies/Sensitivity

Immunoglobulins (IgE, IgG, IgM, IgA)	Serologic antibody screening tests; testing of Immunoglobulins; Total IgE ELISA; RAST (radioallergosorbent-blood IgE); Bloodspot: IgG Provocative specific antigen skin prick: (IgE related skin response) used to diagnose allergy and identify the allergen.	Used to determine immunodeficiency states; measurement of +IgE = allergic disorders; (see Table 27-3) +IgG = delayed immunologic sensitivity or intolerance response (see Table 27-3). IgA = largest % Ig primarily made in GI lymphoid tissue and marker of immune strength and response.	Total IgA: Adults = 85-385 mg/dL Children = 1-350 mg/dL Total IgG: Adults = 565-1765 mg/dL Total IgE = <10 IU/L RAST IgE = <1 low allergic risk Total IgM: Adults 55-375 mg/dL Children 20-200 mg/dL Total IgD = minimal	NSAIDS, glucocorticosteroids, vitamin C, bioflavonoids can suppress the immunologic response and promote a false negative. IgA used as a biomarker reference of adequate immune response to enable measurement of IgG, IgE, IgM.
Innate Immune Factors				
Total Leukocyte Count (TLC)	Calculated from the percentage of lymphocytes reported in the hemogram and the WBC count. Units = cells/ $\mu$ l or cells/mm <sup>3</sup>	Decreased in protein-energy malnutrition and immunocompromised state.	Normal: >2700 Moderate depletion: 900-1800 Severe depletion: <900	Usefulness in acute care limited by drugs, effect of aging and disease (metabolic, malignant, and infectious diseases); difficult to administer and interpret results; semiquantitative.
Delayed cutaneous hypersensitivity	Anergy for antigens, such as mumps and <i>Candida</i> ; occurs in malnutrition; antigens injected intradermally; redness (erythema) and hardness (induration) read 1, 2, or 3 days later.	Response affected by protein-energy status and vitamin A, iron, zinc, and vitamin B <sub>6</sub> deficiencies.	<i>Induration</i> 1+: <5 mm 2+: 6-10 mm 3+: 11-20 mm 4+: >20 mm	Erythema present or absent Cytokine examples: IL-1 IL-6 IL-8 IL-10 TNF- $\alpha$ TH-1 TH-2 (per lab references)
Cytokines	Serum or joint fluid proteins tested from venous blood. They include lymphocytes, (T & B cells), monocytes, leukocytes (interleukins), eosinophils, interferon and growth factors. (See Chapter 8)	A group of immune reactant proteins that have many functions even from one cell to another. They respond to the environmental influences to communicate and orchestrate the immune response to protect from cancer, infection and inflammation.	Blood: 1% to 3% BAL 50-500/mm <sup>3</sup> BAL negative for infection CSF < 10 mm <sup>3</sup>	Because of the nonspecific nature of blood eosinophilia, it can require further clinical investigation to determine the causal agent.
Adaptive Immune Factors				
Eosinophils (Eosinophil leukocyte)	Blood: BAL fluid CSF specimen to rule out eosinophilic meningitis.	Blood: Wide range of clinical conditions reflect nonspecific eosinophilia; elevated related to possible allergies, asthma, sensitivities, or cancers; particularly elevated eosinophils are found with intestinal parasites; noninfectious conditions.	Blood: 1% to 3% BAL negative for infection CSF < 10 mm <sup>3</sup>	
Food Intolerance/Sensitivity Panels				
Antigen Lencocyte Cellular Antibody Test (ALCAT)	Measurement of leukocyte cellular reactivity in whole blood, measures levels of mediators by blood cells presented with food or chemical antigens; measures relative changes in cell size (see Table 27-3)	Food and chemical non-IgE sensitivity (intolerance) testing for up to 350 foods plus gliadin/gluten, casein/whey, and candida albicans; food additives, molds, environmental chemicals, pharmacocapeutic agents, and other suspected items upon request.	350 Foods: Acceptable Foods Mild Intolerance Moderate Intolerance Severe Intolerance Candida/gliadin-casein-whey, chemicals/molds:	No Reaction Mild, Moderate or Severe Reaction

Continued

## APPENDIX 30. Laboratory Values for Nutritional Assessment and Monitoring—cont'd

Test	Principles	Interpretation	Reference Range	Limitations and Implications
Mediator Release Test (MRT) (immunologic food reaction test)	Untreated whole blood assay; sample is divided into 150 aliquots plus control samples and incubated with a precise dilution of pure extract of a specific food or food additive <sup>c</sup> (see Chapter 27).	Non IgE-mediated reactions; measurement of blood components; blood specimen checked against the specific signs of cell-mediated reactivity to the antigen challenged (imminent or actual mediator release). See Table 27-3.	Normal = negative Mild, moderate or severe reactions are delineated.	NSAIDS, glucocorticosteroids, vitamin C, bioflavonoids can suppress the immunologic response and promote a false negative. IgA used as a biomarker reference of adequate immune response to measure. Any of the celiac tests 2–10 tests should be compared with baseline IgA serum levels and presence of immune suppressive medications to rule out IgA deficiency, which can skew test results to false negative because of compromised or suppressed immune response. Undiagnosed celiac is associated with increased incidence of all chronic diseases and shortened lifespan. <sup>10,11,12</sup>
Celiac Panel/Gluten Sensitivity Panel	1. Immunologic and genomic for celiac or gluten sensitivity-related genes.	Measurements to identify a possible genetic or immunologic disease of the small bowel in response to exposure to gluten or gliadin molecules in diet. Continued long-term exposure to gluten or gliadin molecules promotes nutrient deficiencies and insufficiencies.	See celiac tests 2–10.	Sensitivity/Specificity 90+%/95%
2. Endomysial antibodies (EMA)	High specificity for celiac disease; may obviate need for small bowel biopsy for diagnosis; become negative on gluten-free diet;	EMA negative		
3. Tissue Transglutaminase (tTG-IgA, tTG-IgG)	Autoantigen of Celiac disease, tTG is indicative of villous atrophy secondary to gluten exposure causing damage to GI small intestine villi. tTG negative test results indicate gluten-free diet compliance; marker of restoration of GI villi tight junctions and small bowel villi integrity.	tTG IgA negative tTG IgG negative		Sensitivity/specificity 98%/95% in adults; 96%/99% in children. Best age to begin measuring tTG is age 2–3 years. <sup>13</sup>
4. Antigliadin antibodies (AGA IgA, AGA IgG)	Positive results are evidence of immune response to the gliadin proteins in gluten-containing foods.	AGA IgA negative AGA IgG negative		Lowest sensitivity among celiac panel (70%–85%) and specificity (70%–90%) for celiac. Also useful for non-celiac gluten sensitivity.
5. Deamidated gliadin peptide (DGP)	DGP antibodies improve <sup>14</sup> diagnostic accuracy for diagnosis of CD when tested with tTG; proteins present in the submucosa of affected person's bond to deamidated peptides to form molecular complexes that stimulate the immune system.	DGP negative		Specificity varied between 97.3% and 99.3%. Sensitivity of IgG anti-DGP significantly better than that of IgG anti-tTG ( $p < 0.05$ ). Specificity was significantly better than IgA and IgG AGA. <sup>15</sup>
6. Celiac genetic HLA haplotype HLA-DQ2 HLA-DQ8 Cellular assay/MLC to test HLA class II types	HLA-DQ2 and HLA-DQ8 positive indicates a low positive predictive value but a very high negative predictive value for celiac disease. Higher prevalence of CD in patients with Type 1 DM or autoimmune thyroid disease (2%–4%) than in general population	Genotype: HLA DQ2 negative HLA DQ8 negative		More than 97% of individuals with celiac disease share the two HLA markers DQ2 and DQ8, which have high sensitivity and poor specificity. One of the markers can increase possible non-celiac gluten sensitivity (e.g., Type 1 DM DQA1*0501:DQB1*0201 haplotype). <sup>14,15,16</sup>

<p><b>7. Wheat/Gluten Proteome Reactivity &amp; Autoimmunity</b></p> <p>Functional medicine serum lab tests to broaden the view of celiac and gluten sensitivity by assessing antibody production against an array of protein, enzyme and peptide antigens; includes <i>glutens, lectins, opioids</i> and the enzyme <i>glutamic decarboxylase (GAD65) IgG, IgA.</i></p> <p>Available from <a href="http://www.cyrexlabs.com">www.cyrexlabs.com</a>.</p>	<p>ELISA Index</p> <p>Wheat</p> <p>IgG 0.30-1.30 IgA 0.40-2.40</p> <p>Agglutinin</p> <p>IgG 0.30-1.50 IgA 0.90-1.90</p> <p>Alpha Gliadin 17 MER</p> <p>IgG 0.30-1.50 IgA 0.60-2.00</p> <p>Alpha Gliadin 33 MER</p> <p>IgG 0.30-1.40 IgA 0.60-1.80</p> <p>Gamma Gliadin 15 MER</p> <p>Omega Gliadin</p> <p>IgG 0.50-1.60 IgA 0.60-1.80</p> <p>Glutenin</p> <p>IgG 0.20-1.50 IgA 0.50-1.70</p> <p>Gluteomorphin</p> <p>IgG 0.30-1.50 IgA 0.60-1.80</p> <p>Prodynorphin</p> <p>IgG 0.40-1.70 IgA 0.60-1.80</p> <p>GAD65</p> <p>IgG 0.40-1.30 IgA 0.80-1.50</p>	<p>Enhances clinical sensitivity and specificity in detection of celiac and gluten sensitivity reactions</p> <p>Assists further dietary evaluation for celiac or gluten sensitive individuals that are non-responsive to a gluten-free diet; can relate to gut dysbiosis and continued GI inflammation.</p> <p>Available from <a href="http://cyrexlabs.com">cyrexlabs.com</a>.</p>
<p><b>8. Gluten-Associated Cross-Reactive Foods and Foods Sensitivity IgG + IgA Combined</b></p> <p>Cow's Milk</p> <p>Alpha-Casein &amp; Beta-Casein</p> <p>Casomorphin</p> <p>Milk Butyrophilin</p> <p>American Cheese</p> <p>Chocolate</p> <p>(Others available)</p>	<p>Functional medicine serum lab tests to assess IgG and IgA immune antibody reactions to known cross-reactive food antigens, with the most common being casein. Other foods included are: sesame, hemp, rye, barley, polish wheat, buckwheat, sorghum, millet, spelt, amaranth, quinoa, yeast, tapioca, oats, coffee, corn, rice, potato.</p> <p>Gold standard for diagnosis of celiac disease. Recommended to correlate with positive serology.</p>	<p>Negative</p> <p>Normal increase: &lt;50 parts/million (i.e., &lt;50 ppm)</p>
<p><b>9. Biopsy, small bowel/jejunal (Others available)</b></p>		
<p><b>Lactose Intolerance</b></p>	<p>Hydrogen Breath Test for Lactose (HBT-lactose)</p>	<p>Bacterial overgrowth can cause false-positive results; consumption of soluble fiber or legumes and smoking are associated with H<sub>2</sub> production; false-negative results caused by antibiotics.</p>

### III. Tests of Carbohydrate Absorption

## APPENDIX 30. Laboratory Values for Nutritional Assessment and Monitoring—cont'd

Test	Principles	Interpretation	Reference Range	Limitations and Implications
Lactose tolerance test	Lactose loading (50 g) followed by blood sampling at 5, 10, 30, 60, 90, and 120 min after dose; glucose produced from lactose is assayed.	Lactase deficiency associated with <20 mg/dL increase in glucose.	Normal glucose increase >20 mg/dL	Test is not specific (many false positives) or sensitive (many false negatives).
Fructose Intolerance Hydrogen Breath Test-Fructose (HBT-fructose)	An assessment for the change in the level of hydrogen and/or methane gas is diagnostic for fructose malabsorption.	HBT-fructose can be used to diagnose a mutation in the adolase B gene. If hereditary fructose intolerance, may result in gastrointestinal symptoms and hypoglycemia. (Guery 2007)	Normal increase <20 parts/million (<20 ppm) Positive BHT-fructose >20 parts per million (>20 ppm)	Positive test results indicate probable benefit of a fructose-restricted diet; research supports use in abdominal pain, IBS, gout, and unexplained liver disease.
Fructose Sensitivity	Blood lymphocyte specimen grown with a mitogen to measure growth by incorporating tritiated radioactive thymidine into the DNA of the cells	Functional intracellular metabolic test of possible in-born errors compromising fructose metabolism like fructose-6-phosphate (Vantyghem 2009)	> 34% (valid for male and female of 12 years or older)	Rule out fructose sensitivity in hypoglycemia of unknown etiology, overweight, obesity.
<b>IV. Tests of Lipid Status</b>				
<b>Lipids</b>				
Cholesterol, Total serum or plasma (CHOL)	CHOL is enzymatically released from cholesterol esters; fasting test	Total CHOL correlated with risk for cardiovascular diseases but not as good an indicator as HDL-c and LDL-c. See NCEP guidelines.	Desirable: <200 mg/dL (<5.2 mmol/L) Borderline: 200-239 mg/dL (5.2-6.2 mmol/L) High risk: 240 mg/dL (6.2 mmol/L) Lower limit: 120 mg/dL (3.0 mmol/dL)	Cholesterol measurements have considerable within-subject variability. May partly result from variability in specimen collection or handling.
High Density Lipoproteins (HDL-c)	LDL-c (and VLDL-c) are precipitated from the serum before measurement of residual of particle size HDL-c; direct measurement of HDL-c is now done in some laboratories.	HDL-c is called "good cholesterol" to indicate that it is protective against atherosclerotic vascular development, or a negative risk factor	Desirable: Men >40 mg/dL (>1 mmol/L) Women >50 mg/dL (>1.25 mmol/L)	Some precipitation methods cause underestimation of HDL. HDL can be divided into classes: HDL <sub>1</sub> , HDL <sub>2</sub> , and HDL <sub>3</sub> ; Elevated HDL <sub>3</sub> correlates with risk of CVD.
Low Density Lipoproteins (LDL-c)	LDL-c is estimated by the Friedewald formula, LDL-c = total cholesterol – HDL-c – TG <sub>5</sub> , or by new direct assays.	LDL-c is called "bad cholesterol" to indicate that it is a positive risk factor for CVD. See NCEP guidelines.	Desirable: <100 mg/dL (<2.59 mmol/L) Borderline: 130-159 mg/dL (3.4-4.1 mmol/L) High risk: >160 mg/dL (>4.1 mmol/L)	Calculation only valid when TG concentration is <400 mg/dL, cannot be determined in nonfasting serum or plasma. Direct assay methods preferred.
	Available lipid particle size testing examples: <a href="http://www.privateMDLab.com/VAP(tm)">www.privateMDLab.com/VAP(tm)</a> <a href="http://www.BerkeleyHeartLab.com">www.BerkeleyHeartLab.com</a>	Pattern B (small, dense LDL-C) is associated with increased risk of CHD and is responsive to diet. Pattern A (larger, buoyant LDL) is not associated with risk.	Women: 40-160 mg/dL (0.45-1.81 mmol/L) Men: 35-135 mg/dL (0.40-1.55 mmol/L)	
Triglycerides (TGs)	Lipases release glycerol and fatty acids from TGs;	The association of TGs and CHD has been shown. Elevated TG increases blood viscosity.	<150 mg/dL normal 150-199 mg/dL Borderline high 200-399 mg/dL High >500 mg/dL very high	Fasting specimen is essential; sugar concentrated foods and alcohol ingestion can increase; some anticoagulants may affect TG level.
<b>Fat Malabsorption</b>				
Fecal fat screening	Microscopic inspection of fat-stained (Sudan stain) specimens for the presence of lipid droplets.	Trained observers are able to identify excess fat in ~80% of persons with fat malabsorption.	Qualitative results	Patient must be consuming sufficient fat for analysis to reveal malabsorption. Semiquantitative.

Prothrombin time (PT)	Fat malabsorption decreases absorption of fat-soluble vitamins A,E,D,K. Beta-Carotene; low vitamin K levels impair coagulation, causing a prolonged PT. (also can be called INR (international normalized ratio))	A prolonged PT is a relatively sensitive but nonspecific indicator of the fat-soluble vitamin K from fat malabsorption.	10-15 sec INR: 0.8-1.1 Possible critical value: > 20 sec. INR: > 5.5	'Tests effected by oral anticoagulants and other drugs, reduced platelet count, acquired and hereditary bleeding diseases, and liver disease PT.
Quantitative fecal fat determination	Patient must consume 100 g fat/day (4-8 oz whole milk/day, and 2 Tbsp vegetable oil/meal) during and for 2 days before collection	Quantitative 72-hour stool collection required for accurate assessment; average daily discharge used for interpretation.	Normal: <5 g fat/24 hr Malabsorption: >10 g/24 hr	Failure to adhere to the diet invalidates the results.
Carotene, Serum Total) (CARO)	Carotenoids, fat-soluble pigments in plant foods, poorly absorbed in fat malabsorption; light sensitive; transport specimen in amber transport tube; Quantitative Spectrophotometry testing. See Raman Spectroscopy, Chapter 27.	A CARO level of less than 50 mg/dL is seen in ~85% of patients with fat malabsorption.	50-200 mcg/dL (0.74-3.72 nmol/L)	Decreased CARO levels or Low spectrophotometry score are also seen in those with low vegetable and fruit diets (e.g., in TPN or tube feeding), liver failure, celiac disease, cystic fibrosis, human immunodeficiency virus, and some lipoprotein disorders.
Vitamin A, D, E, K Fatty acid analysis	See V. Tests of Micronutrient Status. Whole blood or RBC levels of ALA (C18:3n3) and LA (C18:2n6) reflect essential fatty acid status; Also, complex relationships regarding fatty acid analysis are known in lipid biochemistry-related to neurological and inflammatory diseases, cell membrane dysfunction and genetic disorders <sup>17,18</sup>	RBC fatty acid shown to associate with fatty acid tissue composition. Plasma fatty acid is associated with fat dietary or supplement intake or fat digestion and absorption. Endogenous synthesis assessed by eicosapentaenoic (EPA) (C20:3n9); DHA(C22:4n3); DGLA (C20:3n6) Ratio supports neurologic integrity and inflammation control; plasma phospholipid C20:3n9/C18:2n6 ratio used to assess status.	C20:3n9/C18:2n6 ratio >0.2 confirms imbalance of EPA:DHA general Reference 1:1. Omega 6:3 between 1:1 and 4:1.	Is not specific for risk of atherosclerotic disease; inflammation influences this fatty acid test. Likely causes are minor injuries, trauma, and other. Bacterial infections, periodontal/cavitations, orodental disease, <sup>19</sup> <i>chlamydia pneumoniae</i> , <sup>20</sup> and central adiposity <sup>21</sup>
Thiamin (B <sub>1</sub> ) <sup>c</sup>	Thiamin status is usually assessed by measuring the amount of TPP needed to fully activate the RBC enzyme transketolase.	The TPP needed to fully activate transketolase is inversely related to B <sub>1</sub> status; percent stimulation by TPP.	Normal: 70-200 nmol/L (for individuals not taking thiamine (B1)) Stimulation >20% (index >1.2) indicates deficiency % Stimulation >40% (index >1.4) indicates deficiency	Amount (and activity) of enzyme affected by drugs, iron, folate, or vitamin B <sub>12</sub> status, malignant or GI diseases, and diabetes.
Riboflavin (B <sub>2</sub> )	Riboflavin status is assessed by measuring the amount of FAD needed to fully activate RBC enzyme GR	The FAD needed to fully activate GR is inversely related to B <sub>2</sub> status; percent stimulation.	% Stimulation >40% (index >1.4) indicates deficiency	Amount or activity of enzyme may change with age, iron status, liver disease, and glucose-6-phosphate dehydrogenase deficiency.
Niacin (B <sub>3</sub> ) <sup>d</sup> Pyridoxine (B <sub>6</sub> ) <sup>e</sup> PLP compounds	No tests have been developed. <sup>d</sup> 1. RBC enzymes, ALT (SGPT) or AST (SGOT), <sup>e</sup> are assayed for the presence of PLP as the enzymes' cofactor. 2. Plasma PLP can be directly measured by chromatography.	1. Difference between enzyme activities before and after addition of PLP is inversely related to B <sub>6</sub> status. 2. PLP is major transport form of B <sub>6</sub> ; therefore serum levels reflect body stores.	1. % ALT stimulation of >25% or AST activity of >50% in deficiency 2. Normal: 0.50-3.0 mcg/dL (20-120 nmol/L)	1. Disease and drugs that affect the liver and heart and pregnancy confound interpretation. 2. Deficiency may be seen clinically before plasma PLP levels decrease.

Continued

## APPENDIX 30. Laboratory Values for Nutritional Assessment and Monitoring—cont'd

Test	Principles	Interpretation	Reference Range	Limitations and Implications
Folate <sup>6</sup>	<p>3. Trip load test, measures excretion of the PLP-dependent metabolite xanthurene acid (XA). 24 hour urine collection required.</p> <p>1. Because of ↓ DNA synthesis, large RBCs are produced.</p> <p>2. Shape of neutrophil nucleus affected by folate deficiency.</p> <p>3. Blood folate levels can be directly measured by radioimmunoassay.</p> <p>4. Functional folate status assayed by FIGLU in 24-hour urine or after oral histidine loading.</p> <p>5. Single Nucleotide Polymorphisms (SNPs) MTHFR 677C MTHFR1298C</p>	<p>3. In this functional test the levels of urinary XA should decrease significantly when 3–5 g of L-TriP is ingested if marginal vitamin B<sub>6</sub> status</p> <p>1. Deficiency leads to increase in MCV (macrocytic sized RBCs)</p> <p>2. Neutrophil lobe count seen in folate deficiency.</p> <p>3. Both RBC and serum folate are indicators of body stores.</p> <p>4. After 2–15 g loading dose, 10–50 mg of FIGLU should be excreted in 8 hours.</p> <p>5. SNPs of compromised methylation (transfer of methyl groups in metabolism) potential in use and conversion of folate or folic acid intracellularly. See Chapter 5.</p>	<p>3. Marginal status: &gt;50 mg/24 hr</p> <p>1. Normal: MCV &lt;100</p> <p>2. Normal: &lt; or equal 4 lobes per neutrophil</p> <p>3. 2–10 mcg/L serum; 140–960 ng/L RBC (3.2–22 nmol/L)</p> <p>4. Normal: &lt;7.4 mg/24 hours (&lt;42.6 mmol/24 hr) without loading</p> <p>MTHF 677C/1298C Normal = Wild type –/–</p>	<p>3. Steroid drugs and estrogen enzyme activity; some drugs cause analytic errors. Trip load test most sensitive and responsive to functional adequacy of B6.</p> <p>1. Not sensitive or specific for folate.</p> <p>Possible involvement with B<sub>6</sub>, B<sub>12</sub>, SAMe and other cofactors in the methionine pathway.</p> <p>2. Lobe count sensitive but not specific.</p> <p>3. Plasma from nonfasted subjects may reflect recent intake; RBC folate is not measured accurately.</p> <p>4. FIGLU affected by vitamin B<sub>12</sub>, drugs, liver disease, cancer, tuberculosis, and pregnancy.</p> <p>Other SNPs are known that affect methylation metabolism: COMT, CYP1B1, and other cytochrome enzymes. See Chapter 5.</p> <p>1. Not sensitive or specific for B<sub>12</sub>.</p> <p>2. Lobe count sensitive but not specific.</p> <p>3. Marginal deficiency not correlated with level.</p> <p>4. Specific for B<sub>12</sub> but requires normal BCAA levels; available at most laboratories.</p> <p>5. Test must be repeated with oral administration of intrinsic factor (IF) to differentiate IF deficiency and malabsorption.</p> <p>Hcy and LDL cholesterol risk is increased even at slightly elevated levels.</p> <p>Hcy has a strong association with degenerative neurologic conditions like Parkinson's disease and dementias.</p> <p>Hcy suggests poor methylating capacity of client with need for increased intake of folic acid, B<sub>6</sub>, B<sub>12</sub>, and SAMe.</p> <p>Blood samples must be carefully prepared for assay to prevent C breakdown.</p> <p>Oxalate, glucose, and proteins interfere with some assays; recent intake can mask deficiency.</p>
Cobalamin (B <sub>12</sub> )	<p>1. Because of low B12 resulting in decreased DNA synthesis, large RBCs are produced.</p> <p>2. Shape of neutrophil nucleus is affected by B<sub>12</sub> deficiency.</p> <p>3. B<sub>12</sub> can be directly measured by radioimmunoassay.</p> <p>4. Methylmalonic acid excretion reflects a functional test of B<sub>12</sub> availability for BCAA metabolism.</p> <p>5. Schilling test for intrinsic factor and B<sub>12</sub> absorption assesses radiolabeled B<sub>12</sub> absorption as reflected by urinary excretion.</p> <p>6. Homocysteine (Hcy)</p>	<p>2. Increased neutrophil lobe count in B<sub>12</sub> deficiency.</p> <p>3. Levels &lt;150 ng/L indicate deficiency (age affects level).</p> <p>4. Methylmalonic acid (MMA) excretion &gt;300 mg/24 hr in B<sub>12</sub> deficiency. Sensitive test without being overly specific.</p> <p>5. Abnormal B<sub>12</sub> absorption indicated by excretion &lt;3% of B<sub>12</sub> radioactivity per 24 hours.</p> <p>Hcy level is an independent risk factor for CVD, venous thrombotic disease, and other diseases; folic acid and vitamins B<sub>12</sub> and B<sub>6</sub> reduce plasma Hcy levels. Total Hcy (oxidized + reduced forms) is an intermediate amino acid in methionine metabolism.</p>	<p>2. Normal: &lt; or equal 4 lobes per neutrophil</p> <p>3. 160–950 pg/mL (118–701 pmol/L)</p> <p>4. Normal excretion: 5 mg/24 hr (42 mmol/24 hr) Serum MMA -0.08–0.56 nmol/L (Normal &lt; 105 ng/mL)</p> <p>5. Normal excretion: ~8% of radioactivity per 24 hours</p> <p>Optimum levels suggested 4–7 mmol/L</p>	<p>2. Lobe count sensitive but not specific.</p> <p>3. Marginal deficiency not correlated with level.</p> <p>4. Specific for B<sub>12</sub> but requires normal BCAA levels; available at most laboratories.</p> <p>5. Test must be repeated with oral administration of intrinsic factor (IF) to differentiate IF deficiency and malabsorption.</p> <p>Hcy and LDL cholesterol risk is increased even at slightly elevated levels.</p> <p>Hcy has a strong association with degenerative neurologic conditions like Parkinson's disease and dementias.</p> <p>Hcy suggests poor methylating capacity of client with need for increased intake of folic acid, B<sub>6</sub>, B<sub>12</sub>, and SAMe.</p> <p>Plasma: 0.5–1.4 mg/dL (30–80 nmol/L)</p> <p>Leukocyte deficiency: 20–50 mcg/10<sup>8</sup> WBCs (1.1–3 fmol/cell)</p>
Ascorbic acid (C)	<p>Plasma or leukocyte C measured by (1) chromatography; (2) by ascorbate oxidase; (3) spectrophotometrically by reaction with 2,4-dinitrophenylhydrazine.</p>	<p>Leukocyte C is less affected by recent intake, but well-fasted plasma levels parallel leukocyte levels; plasma preferred for acutely ill patients because leukocyte level is affected by infection,<sup>22</sup> some drugs, and hyperglycemia; &lt;0.2 mg/dL (&lt;10 mcg/10<sup>8</sup> WBC)</p>	<p>Plasma: 0.5–1.4 mg/dL (30–80 nmol/L)</p> <p>Leukocyte deficiency: 20–50 mcg/10<sup>8</sup> WBCs (1.1–3 fmol/cell)</p>	

<b>Retinols (A)</b>	Serum retinol and retinol esters; functional tests (e.g., dark adaptation) only detect severe deficiency; Age and sex important determining factors for normal retinol levels.	Retinol levels <20 mcg/dL (<0.7 mmol/L) indicate severe deficiency; specific levels are being determined for placental/ newborn deficiency serum levels.	Normal: 20 to 100 mcg/dL (0.7-3.5 mmol/L) Suboptimum (NHANES II/Gibson): Age 3-11 y: < 0.35 mmol/L Age 12-17 y: < 0.70 mmol/L Age 18-74 mmol/L 0.70-1.05 mmol/L Pregnancy 0.79-1.91 mmol/L Upper Limit: 3.5 mmol/L	Exposure of serum to bright light or oxygen destroys vitamin A; low RBP level is associated with low vitamin A, zinc and iron (see protein-energy section). Vitamin A's gene transcription is on the nuclear RXR; <sup>22</sup> the vitamin D receptor forms a heterodimer, requiring balance between vitamins A & D for optimum function.
<b>Tocopherols (E)</b>	Serum alpha- and beta-gamma-tocopherols serve different antioxidant functions. Growing evidence beta-gamma tocopherol may be more important than alpha-tocopherol for human vitamin E nutrition.	Lower values found in infants. Interpretation requires monitoring lipid levels; if hyperlipidemia calculate plasma alpha-tocopherol: cholesterol mmol/L ratio >2.2 or alpha-tocopherol <5 mg/L indicates risk of vitamin E deficiency. <sup>23</sup>	Normal: alpha-tocopherol 5.7-20 mg/L beta-gamma-tocopherol 4.3 or less mg/L	Plasma level depends on recent intake and level of lipids, especially TGs, in blood. Smoking and BMI also negatively effect tocopherol levels.
<b>Cholecalciferol / (D<sub>3</sub>) (D<sub>2</sub>) Ergocalciferol</b>	1. Alkaline phosphatase activity reflects level of bone activity and indirectly vitamin D status. (see further discussion of ALP in Liver Enzymes section).  2. CholeCalcidiol (D3 25OH-D) and ergocalciferol (D2 25OH-D).  3. Calcitriol (1,25-[OH]2-D <sub>3</sub> )	2. <20 ng/mL (7.4 nmol/L) indicates deficiency; >200 ng/mL (500 nmol/L) indicates hypervitaminosis D.	Adult: 25-100 U/L Child 1-12 yr: <350 U/L	1. Not specific, but a sensitive indicator; serum Ca and PO <sub>4</sub> should also be evaluated. Zinc and B <sub>12</sub> are rate-limiting co-enzymes for production of alkaline phosphatase; therefore low levels < 40 U/L suggest possible zinc or B <sub>12</sub> or intrinsic factor insufficiencies.  2. Best indicator of status (liver stores), but marginal levels hard to interpret. <sup>24</sup> Increased BMI and body fat% may reduce serum D3 25OHD.
		3. Used to show that vitamin D metabolism is occurring normally; Active vitamin D to signal nuclear RXR receptor.	2. 15-80 mcg/L summer (37-200 nmol/L) 14-42 mcg/L winter (35-105 nmol/L)	3. 2.5-4.5 ng/dL (60-108 pmol/L) (little seasonal change)
<b>25-hydroxyvitamin D (25(OH)D) / Calcidiol/ Calcidiol</b>	Prohormone Vitamin D malabsorption can lead to secondary malabsorption of calcium. Vitamin D supplementation can lead to increased absorption of calcium and phosphorus; contraindications of supplementation for individuals with kidney or gall stones, sarcoidosis, tuberculosis, lymphoma, or when become hypercalcemic with vitamin D supplementation.	Vitamin D insufficiency is defined as the lowest threshold value for plasma 25OHD that prevents secondary hyperparathyroidism, bone turnover, bone mineral loss, or seasonal variations in plasma PTH.	In K1 deficiency, PT increases with increasing production of abnormal coagulation factors. <sup>h</sup> K1 vegetable plant source; drug-nutrient interaction with blood thinners. K2 animal and bacterial fermented sources. K3 synthetic form of Vitamin K <sub>1</sub> .	K1: 0.13-1.19 ng/mL (0.29-2.64 nmol/L) K2: (not commercially available—see K2 marker, Osteocalcin, below)
<b>Phylloquinone (K<sub>1</sub>) and Menaquinoneone (K<sub>2</sub>) Menadione (K<sub>3</sub>)</b>	Normal coagulation factor synthesis requires K1; PT assesses coagulation status. K2 primarily involved with calcium metabolism, including bone health.	In K1 deficiency, PT increases with increasing production of abnormal coagulation factors. <sup>h</sup> K1 vegetable plant source; drug-nutrient interaction with blood thinners. K2 animal and bacterial fermented sources. K3 synthetic form of Vitamin K <sub>1</sub> . vitamin precursor to Vitamin K2 known as a provitamin.	K1: 0.13-1.19 ng/mL (0.29-2.64 nmol/L)	The level of vitamin K available for vitamin K-dependent bone proteins may not be reflected by the PT; test references vary significantly with method.

Continued

## APPENDIX 30. Laboratory Values for Nutritional Assessment and Monitoring—cont'd

Test	Principles	Interpretation	Reference Range	Limitations and Implications
Osteocalcin (OC) / undercarboxylated osteocalcin (ucOC) (K2 marker)	Serum noncollagenous protein specific for bone and dentin formation and turnover. Functional marker of vitamin K2, a rate-limiting cofactor of formation of osteocalcin. (Also known as Bone Gla Protein). One of the osteocalcin fragments, undercarboxylated osteocalcin, is most sensitive K2 marker and associated with risk of fracture.	Can be used as a marker of metabolic trend, suggesting low or high vitamin K2; useful in assessing need for a vitamin K2 rich diet or K2 supplementation to optimize formation of intracellular bone osteocalcin; inhibit soft tissue calcification, and other uses for K2. OC/ ucOC considered more sensitive markers of bone activity than alkaline phosphatase during corticosteroid therapy.	0-11-50 ng/mL ucOC: Normal < 1.65 ng/mL High > 1.65 ng/mL NOTE: Elevated levels associated with low Vitamin D25OH levels	Vitamin K2 is not as involved with coagulation as K1. Vitamin K2 is important in calcium metabolism and therefore calcium and vitamin D status. There is a synthetic vitamin K3 that has similar actions as K2 being used as adjunctive to integrative cancer therapy usually administered IV.
<b>B. Minerals</b>				
<i>Electrolytes</i>				
Sodium ( $\text{Na}^+$ ) Potassium ( $\text{K}^+$ ) Chloride ( $\text{Cl}^-$ ) Bicarbonate or total $\text{CO}_2$	Serum electrolytes, including bicarbonate, are usually measured together by ion-specific electrodes in autoanalyzers; sometimes Na and K are measured by flame emission spectrophotometry. <sup>j</sup>	Elevated serum Na seen in water loss; decreased serum Na and K occurs in diarrhea and poor dietary intake or cellular uptake. Decreased chloride levels with changes with in cation and osmotic changes in the body; Bicarbonate levels reflect acid-base balance.	135-145 mEq/L (135-145 mmol/L) 3.5-5 mEq/L (3.5-5 mmol/L) 100-110 mEq/L (100-110 mmol/L) 21-30 mEq/L (21-30 mmol/L)	Electrolytes change rapidly in response to changes in physiology (e.g., hormonal stimulus, renal and other organ dysfunction, acid-base balance changes, and drug action); serum electrolytes are minimally affected by diet.
<i>Major Minerals</i>				
Calcium ( $\text{Ca}^{2+}$ )	1. Total serum $\text{Ca}^{2+}$ (bound and unbound)  2. Ionized (free) $\text{Ca}^{2+}$	Usually slightly more than half of the serum $\text{Ca}^{2+}$ is bound to albumin or complexed with other molecules; the remaining $\text{Ca}^{2+}$ is called <i>ionized Ca (ICa)</i> ; ICA is available physiologically. Elevated IgE and mast cell release increases intracellular calcium ion levels and negatively distributes ICA. When interpreting ionized calcium, important to consider other related markers: osteocalcin, vitamin D25 and D1,25OH, and vitamin A retinol.	1. 8.6-10 mg/dL (2.15-2.5 mmol/L)  2. 4.64-5.28 mg/dL (1.16-1.32 mmol/L)	Calcium status is related to many factors, including vitamin D, vitamin K2, phosphate, parathyroid function, malignancy, and renal function; medications (thiazide diuretics, lithium, vitamin A toxicity).
Phosphate ( $\text{H}_2\text{PO}_4^-$ , $\text{PO}_4^{2-}$ , and $\text{PO}_4^{3-}$ ) (Phosphorus)		Abnormal P level is most closely associated with disturbed intake, distribution, or renal function.	2.7-4.5 mg/dL (0.87-1.45 mmol/L) (higher in children)	If phosphate >3.0 mg/dL, check intake of phosphate-binding medications. Reported as phosphorus (P), not phosphate; hemolyzed blood cannot be used because of high RBC phosphate levels.
Magnesium ( $\text{Mg}^{2+}$ )	1. Total serum $\text{Mg}^{2+}$ measured after reaction to form chromogenic or fluorescent complexes.  2. Ionized (free) $\text{Mg}^{2+}$	Neuromuscular function (hyperirritability, tetany, convulsion, and electrocardiographic changes) affected when levels of total serum $\text{Mg}^{2+}$ fall to <1 mEq/L.	1. 1.3-2.5 mEq/L (0.65-1.25 mmol/L)  2. 0.7-1.2 mEq/L (0.35-0.60 mmol/L)	Usually 45% of the serum $\text{Mg}^{2+}$ is complexed with other molecules; the remaining $\text{Mg}^{2+}$ is called ionized magnesium; serum levels remain constant until body stores are nearly depleted.

<i>Trace Minerals</i>	
Iron CBC <sup>a</sup> and RBC indices	<p>1. HCT = % RBC in whole blood 2. Hgb = blood hemoglobin concentration 3. MCV = mean RBC volume</p> <p>A CBC with RBC indices is one of the first set of tests that a patient receives, although CBC data are not specific for nutrition status, their universal and repeated presence in the patient's record make them very important.</p>
Serum iron (Fe)	<p>Serum Fe<sup>3+</sup> reduced to Fe<sup>2+</sup> and then complexed with chromogen.</p> <p>TIBC determined by saturating serum transferrin with Fe and then remeasuring serum Fe.</p>
Total Iron Binding Capacity (TIBC)	<p>The iron bound globulin protein that responds to the need for iron; half-life ~9 days. (see Chapter 8)</p>
Transferrin (Tf or TfN)	<p>(see Section I:A. Protein Status: Tf)</p> <p>Very sensitive indicator of Fe status; normal RDW reportedly rules out anemia caused by chronic inflammatory diseases.<sup>m</sup> Thalassemia (low MCV, normal RDW) differentiated from iron-deficiency (low MCV, high RDW)</p>
Saturation (Tf-sat or TSAT)	<p>Tf-sat (%) = Serum iron level/TIBC x 100%</p> <p>Measurement of variation in RBC diameter (anisocytosis); reported to be helpful in distinguishing Fe deficiency and anemia associated with chronic inflammation.</p>
RBC Distribution Width (RDW)	<p>The primary intracellular Fe-storage protein; stored mostly in liver; serum levels parallel iron stores;</p>
Ferritin	<p>Best biochemical index of uncomplicated iron deficiency or overload (iron toxicity) and excess storage.</p> <p>Rule out hemochromatosis or pancreatitis if Ferritin &gt;1000 ng/dL (&gt;1000 mcg/L).</p>
Zinc (Zn) <sup>n</sup>	<p>Serum levels measured by atomic absorption spectrophotometry.</p>
<p>1. F: 35%-47% (0.35-0.47)<sup>v</sup> M: 42%-52% (0.42-0.52)</p> <p>2. F: 12-15 g/dL (7.45-9.31 mmol/L) M: 14-17 g/dL (8.44-10.6 mmol/L)</p> <p>3. 82-99 mm<sup>3</sup> (82-99 fL)</p>	
<p>These tests are affected only when iron stores are essentially depleted, and HCT and Hgb are sensitive to hydration status; low MCV also occurs in thalassemias and lead poisoning, as well as iron and copper deficiencies; high MCV suggests macrocytic RBCs and possible inadequate folate, vitamins B<sub>6</sub>, or B<sub>12</sub>.</p> <p>Very insensitive index of total Fe stores; extremely variable (day-to-day and diurnal).</p> <p>TIBC does not increase until Fe stores are essentially completely depleted. TIBC decreases with increased Fe stores needing to rule out excess iron intake or hemochromatosis.</p>	
<p>F: 40-150 mcg/dL (7.2-26.9 mmol/L) M: 50-160 mcg/dL (8.9-28.7 mmol/L)</p> <p>250-400 mcg/dL (45-71 mmol/L)</p> <p>dL</p> <p>Adult male: 215-365 mg/dL (2.15-3.65 g/L)</p> <p>Adult female: 250-380 mg/dL (2.15-3.80 g/L)</p> <p>Newborn: 130-275 mg/dL Child: 203-360 mg/dL</p>	
<p>↓ when Fe stores essentially depleted; low vitamin B<sub>6</sub> and low Tf-sat in aplastic anemia.</p> <p>Chronic illness normal Tf-sat%. Late pregnancy low Tf-sat%.</p> <p>Normal value: 11.0-14.5% Microscopic electronic interpretation required.</p>	
<p>M: 20%-50% F: 15%-50%</p> <p>Iron overload: &gt;400 ng/mL (mcg/L) With anemia of chronic disease: &lt;100 ng/mL (&lt;100 mcg/L) M: 12-300 ng/mL (12-300 mcg/L) F: 10-150 ng/mL (10-150 mcg/L)</p> <p>Females with anemia of chronic disease: &lt;20 ng/mL (&lt;20 mcg/L)</p> <p>6 mos.-15 yr: 7-142 ng/mL (7-142 mcg/L)</p> <p>&lt;1 mo.-5 mos: 50-200 ng/mL (50-200 mcg/L)</p> <p>Newborn: 25-200 ng/mL (25-200 mcg/L) 0.7-1.2 mg/L (11-18 mmol/L)</p>	
<p>Serum levels detect frank—but not marginal—deficiency; blood must be collected in zinc-free tubes.</p>	

Continued

## APPENDIX 30. Laboratory Values for Nutritional Assessment and Monitoring—cont'd

Test	Principles	Interpretation	Reference Range	Limitations and Implications
Copper (Cu)	1. Serum levels measured by flame emission atomic absorption spectrophotometry. 2. Ceruloplasmin is the major Cu-containing plasma protein; measured by immunassay (e.g., nephelometry).	1. Cu deficiency is associated with neutropenia, anemia, and scurvy-like bone disease and megadoses of zinc. 2. Ceruloplasmin is required for conversion of Fe <sup>3+</sup> to Fe <sup>2+</sup> during cellular Fe uptake; anemia can result from low ceruloplasmin; useful marker to follow tetrathiomolybdate™ copper chelation for Wilson's Disease and cancer anti-angiogenesis therapy. <sup>25</sup>	M: 70-140 mcg/dL (11-22 mmol/L) F: 80-155 mcg/dL (13-24 mmol/L) 20 to 35 mg/dL (1.4 mmol/L)	1. Serum levels detect frank but not marginal deficiency; use of oral contraceptives serum Cu. 2. Ceruloplasmin not a useful marker of Cu status but can be used to assess changes in status after supplementation; useful to calculate free copper index with serum zinc and copper as a cancer biomarker. <sup>26,28,29</sup>
Selenium (Se)	1. Serum Selenium test 2. Whole blood levels better reflect long-term status.	Margin between deficiency and toxicity is narrower for Se than any other trace component of the antioxidant enzyme element; important in glutathione peroxidase.	(1) 80-320 mcg/L (1.4 mmol/L) (2) 60-340 mcg/L (0.75-4.3 mmol/L)	Cutoff points for deficiency or toxicity are not well established.
Iodine (I)	Urinary excretion is best indicator of I status, either mcg/24 hr or mcg/g creatinine; thyroid hormone level related to I status. Urine test can use 50 mg I/KI challenge.	Excretion should be >DRT for 24-hour urine or >50 mcg/g creatinine; it can be beneficial to test thyroid hormone and antibodies (TSH, T <sub>3</sub> free, T <sub>4</sub> free, thyroid peroxidase and thyroglobulin antibodies) for improved interpretation; iodine important for other metabolic functions.	No urinary I reference range; T <sub>4</sub> reference range: F: 5-12 mcg/dL (64-154 mmol/L) M: 4-12 mcg/dL (51-154 mmol/L)	Thyroid hormone levels are affected by many factors besides iodine status. Other halogen elements are known antagonists to iodine metabolism; when completing the iodine urine testing, some laboratories will also test for bromine, fluorine, and chlorine.
Creatinine (Cr)	Urinary excretion usually tested by atomic absorption spectrophotometry.	Excretion should be greater or equal to DRI; deficiency reported in patients on long-term TPN; decreased levels in diabetes mellitus.	10-200 ng/dL (1.9-38 nmol/L)	Test not available in most clinical laboratories; special handling required to prevent specimen contamination during collection.
<b>VI. Blood Gases and Hydration Status</b>				
pH	pH = -log [H <sup>+</sup> ]; H <sup>+</sup> depends mainly on the CO <sub>2</sub> from respiration: CO <sub>2</sub> + H <sub>2</sub> O ⇌ H <sub>2</sub> CO <sub>3</sub> ⇌ HCO <sub>3</sub> + H <sup>+</sup> . Measured by ion-selective electrodes (like those found in common pH meters).	In: Acidosis pH <7.35 Alkalosis pH >7.45 pH compatible with life 6.80-7.80.	Whole blood: Arterial: 7.35-7.45 Venous: 7.32-7.42	Blood must not be exposed to air before or during measurement.
Po <sub>2</sub> and O <sub>2</sub> saturation (SaO <sub>2</sub> )	Whole blood O <sub>2</sub> measured by oxygen electrode; Po <sub>2</sub> = "pressure" contributed by O <sub>2</sub> to the total "pressure" of all the gases dissolved in blood	Affected by alveolar gas exchange, ventilation-perfusion inequalities, and generalized alveolar hypoventilation.	Arterial blood: PaO <sub>2</sub> ; 83-108 mm Hg <40 mm Hg = critical value (gravely dangerous) O <sub>2</sub> saturation: 0.95-0.98 (95%-98%) Elderly = 95% Newborn = 40-90%	Blood must not be exposed to air before or during measurement.
PaCO <sub>2</sub>	O <sub>2</sub> Content (CaO <sub>2</sub> ) = O <sub>2</sub> /gm SaO <sub>2</sub> × Hgb (gm/dL) × 1.34 ml + PaO <sub>2</sub> × (.003 ml O <sub>2</sub> /mm Hg/dL) Capacity PaO <sub>2</sub> = FIO <sub>2</sub> (PB-47) - 1.2(PaCO <sub>2</sub> ) Measured by ion-selective electrode; "pressure" contributed by CO <sub>2</sub> to the total "pressure" of all the gases dissolved in blood.	Increased in respiratory acidosis (increased CO <sub>2</sub> in inspired air or decreased in alveolar ventilation) and decreased in respiratory alkalosis (e.g., in hyperventilation from anxiety, mechanical ventilator, or closed head injury [damaged respiratory center]).	Whole blood: Arterial M: 35-48 mm Hg F: 32-45 mm Hg Venous 6-7 mm Hg higher	Blood must not be exposed to air before or during measurement.

Bicarbonate ( $\text{HCO}_3^-$ ) and total $\text{CO}_2$ ( $\text{tCO}_2$ )	For whole blood ( $\text{HCO}_3^-$ ) is calculated from the equation given in pH section.	Increased in compensated respiratory acidosis and in metabolic acidosis; decreased in metabolic acidosis and in compensated respiratory alkalosis.	Whole blood, arterial: 21-28 mEq/L (21-28 mmol/L)	Blood must not be exposed to air before or during measurement.
Osmolality (Osmol)	Osmol depends on amount of particles (solutes) dissolved in a solution; measurement based on relationship between solute concentration and freezing point; serum osmol assesses hydration status and solute load. Specimen midstream clean-catch if infection suspected, or regular collection. Dip Stick or laboratory testing for Specific Gravity.	Osmol increases in dehydration, diabetic coma, diabetic ketoacidosis; also estimated from the formula: $\text{mOsmol/L} = 1.86 \text{ a}(\text{Na}^+) + (\text{Glucose})/18 + (\text{BUN})/2.8$	282-300 mOsmol/kg $\text{H}_2\text{O}$ (1 Osmol = 1 mol of solute particles; 1 kg serum/L)	Freezing point depression gives a more accurate estimate of osmol than the calculated value (e.g., in ketoacidosis).
Urinalysis: Specific Gravity (Sp.Gr.)		One of a multiple of tests on a urine specimen. Sp.Gr. a measure of concentration of particle, electrolytes in the urine; weight of urine: distilled water.	Adult: 1.005-1.030 (usual 1.010-1.025) Newborn: 1.001-1.020	Appearance can also give subjective indication of fluid concentration-high concentration darker in color.
<b>VII. Tests of Antioxidant Status and Oxidative Stress</b>				
Water-soluble compounds	See Vitamin C.	Reference ranges for these compounds vary greatly, depending on the method used for their assay.	See reference for carotenoid range under fat malabsorption	Tests for carotenoids and coenzyme Q are not yet available for routine clinical use.
Lipid-soluble compounds: see Vitamin E	The carotenoids: lutein, xanthine zeaxanthin, alpha- and beta-carotene, and lycopene; carotenoids and coenzyme $\text{Q}_{10}$ (ubiquinone-10) are measured chromatographically.	These assays reflect the presence of all of plasma or serum antioxidants, including vitamins C and E, carotenoids, coenzyme $\text{Q}_{10}$ , glutathione, uric acid, bilirubin, superoxide dismutase, catalase, glutathione peroxidase, and albumin.	These assays are now commercially available but are currently performed only in specialized laboratories. Testing botanicals also available.	8-Isoprostone assays are now commercially available. Markers of oxidative stress are currently assayed only in specialized laboratories.
Carotenoids	ORAC: Oxygen radical absorbance capacity	8-Isoprostone (also called 8-epiprostaglandin $\text{F}_{2\alpha}$ ) increases in plasma or urine of patients with lung disease, hypercholesterolemia, or diabetes mellitus.	Examples: $\alpha$ -tyrosine nitro-tyrosine 8-isoprostone	
Coenzyme $\text{Q}_{10}$	TEAC: Trolox-equivalent antioxidant capacity	8HDG represents whole-body cytosolic and nuclear free radical activity, including status of DNA.	4-hydroxymonenal malondialdehyde Lipid Peroxides	
Total antioxidant capacity (e.g., ORAC, TEAC, FRAP)	FRAP: Ferric-reducing ability of plasma. See Raman Spectroscopy, Chapter 27.	Lipid peroxides is a marker of membrane oxidative damage by ROS to PUFAs of cell membranes.	8-hydroxy-2-deoxyguanosine (8-OHDG) (refer to Laboratory references)	See earlier discussion on phosphate and magnesium.
Oxidative stress markers:	Free radical oxidation products of lipids			
<b>VIII. Tests for Monitoring Nutrition Support</b>				
CRP (see section V. hs-CRP)	CRP is an acute-phase protein used to assess inflammatory status.	Large increases in CRP are associated with development of a catabolic state during the stress response; CRP levels begin to fall when the anabolic phase is entered.	CRP <10 mg/L	Serial values rather than a single value must be used to specify the stage of the stress response.
Chemistry panel with phosphate and $\text{Mg}^{2+}$	Panel includes electrolytes, glucose, creatinine, BUN, and total $\text{CO}_2$ (bicarbonate); see earlier discussion for additional test information.	Used to monitor carbohydrate tolerance, hydration status, and major organ system function.	Very frequently ordered test panel.	
Osmolality	(see discussion in VII. Blood Gases and Hydration Status)			

Continued

## APPENDIX 30. Laboratory Values for Nutritional Assessment and Monitoring—cont'd

Test	Principles	Interpretation	Reference Range	Limitations and Implications
Protein-Energy Balance	(see earlier discussion on PAB, RBP, Tf, ALB, nPCR, Nitrogen Balance, UUN and TUN)			
Minerals: Zn, Cu, Se, Cr	(see earlier discussion of serum zinc, serum copper, ceruloplasmin, and lymphocyte micronutrient testing)			
Vitamins C, D and A	(see earlier discussion of vitamins C, D and A)	Note regarding TPN nutritional monitoring: Vitamin C levels can ↓ sharply in response to stress. Vitamin D and A nuclear receptors share the same connection with the RXR receptor which have synergistic function <sup>27,28</sup> and should be monitored congruently.		Note regarding TPN nutritional monitoring: Systematic, regular monitoring protocol should be followed. Vitamin D25-hydroxy is produced in the liver and can be suppressed with hepatic stress conditions. <sup>29</sup>
Vitamin K1 & K2 status	(TPN only) (see earlier discussion) Contribution of the gut flora to vitamin K status is absent during TPN, and basic TPN formulas are devoid of it.			Important to differentiate between vitamin K1 and K2.
<b>IX. Liver Function Tests</b>				
Bilirubin (BLJ/T/D) (Direct and Indirect)	Total serum bilirubin represents both the conjugated or direct and unconjugated or indirect bilirubin. Elevated levels suggest medical problem.	Conjugated bilirubin levels elevated with cancer of pancreas or liver and bile duct obstruction; unconjugated bilirubin level elevated with hepatitis, jaundice anemias	Total bilirubin: 0.3-1 mg/dL (5.1-17 mmol/L) Indirect bilirubin: 0.2-0.8 mg/dL (3.4-12 mmol/L) Direct bilirubin: 0.1-0.3 mg/dL (1.7-5.1 mmol/L)	Many medications are associated with elevated bilirubin levels.
Alanine Amino Transferase (ALT)	Enzyme found primarily in the liver. (also called serum glutamic pyruvic transaminase (SGPT))	Injury to the liver results in elevated levels of ALT. Depressed in malnutrition.	4-36 U/L Infant: 2 × adult levels	Many medications and alcohol intake are associated with elevated ALT levels. ALT levels are often compared with AST for differential diagnosis.
Gamma-glutamyl transferase (GGT)	Biliary excretory enzyme involved in transfer of amino acids across cell membranes.	Used to evaluate progression of liver disease and screening for alcoholism	F: 4-25 U/L M: 12-38 U/L	Many medications are associated with elevated GGT levels.
Alkaline phosphatase (ALP)	Enzyme found primarily in the bone, liver, and biliary tract; increased in an alkaline environment.	Elevated levels noted in liver and bone disorders.	30-120 U/L	Nonspecific test; other tests need to confirm diagnosis. Many medications are associated with elevated ALP levels.
Aspartate Amino Transferase (AST)	Enzyme primarily found in the heart, liver, and skeletal muscle cells. (also called serum glutamic oxaloacetic transaminase (SGOT))	Diagnostic tool when coronary occlusive heart disease or hepatocellular disease is suspected.	0-35 U/L	Many medications are associated with elevated AST levels. AST levels are often compared with ALT for differential diagnosis.
Alpha 1 Antitrypsin (A1AT)	A1AT is a serine protease inhibitor secreted primarily by hepatocytes; Most common genetic A1AT variants are ZZ, SS, MZ, SZ. (see Table 30-1)	Serum electrophoresis decreased or absent Alpha-1-band. A1AT is an acute-phase reactant associated with emphysema, COPD and cirrhosis of the liver; A1AT elevated with states of inflammation, infection or malignancy.	85-213 mg/dL (0.85-2.13 g/L) Homozygous ++ variants: severe disease early in life. 80 known variants of A1AT gene: Heterozygous ZZ and SS gene variants:	There are 100 known variants of the A1AT gene. <sup>30</sup> If a person is not diagnosed with a severe form as a child, an individual may not be identified until an adult with end-stage lung and liver conditions.
				majority have hepatic or pulmonary symptoms MZ and SZ milder gene variants: rarely have symptoms. <sup>30</sup>

<b>X. Thyroid Function Tests</b>			
Thyroxine T <sub>4</sub> , Total and T <sub>4</sub> , Free	Measures the total amount of T <sub>4</sub> in the blood; free T <sub>4</sub> active form. (see Chapter 32)	T <sub>4</sub> increased in Hyperthyroidism; T <sub>4</sub> decreased in hypothyroidism and malnutrition	T <sub>4</sub> , Total F: 5-12 mcg/dL (64-154 nmol/L) M: 4-12 mcg/dL (51-154 nmol/L)
Triiodothyronine T <sub>3</sub> , Total and T <sub>3</sub> , Free	Measures the total amount of T <sub>3</sub> in the blood; free T <sub>3</sub> active form. (see Chapter 32)	Hyperthyroidism-usually elevated; hypothyroidism-usually decreased and can show low function of thyroid peroxidase enzyme when T <sub>4</sub> normal or high and T <sub>3</sub> low (poor conversion).	T <sub>3</sub> , Total 0.7-1.9 ng/dl (10-23 pmol/L)
Thyroid-stimulating hormone (TSH)	Used to monitor exogenous thyroid replacement or thyroid suppression. (see Chapter 32)	Decreased TSH in Hyperthyroidism; Elevated TSH in hypothyroidism	T <sub>3</sub> , Total 230-619 pg/mL 0.5-5 mIU/L AACF Standards: Target TSH: 0.3-3.0 µIU/mL <sup>o</sup>
Antithyroglobulin antibody (anti-TG)	Anti-TG blood test used as a marker for autoimmune thyroiditis and related diseases. <sup>30</sup>	Anti-TG autoantibodies bind to thyroglobulin affecting thyroid hormone synthesis, storage and release.	Titer <4 IU/mL Anti-TG often tested in conjunction with Anti-TPO test.
	High prevalence of thyroid autoantibodies in celiac and rheumatoid arthritis patients	Recommend investigation of gluten intolerance if elevated Anti-TG.	
Antithyroid peroxidase antibody (Anti-TPO or TPO-Ab)	Anti-TPO blood test used in the diagnosis of thyroid diseases, such as Hashimoto's thyroiditis or chronic lymphocytic thyroiditis (in children). High prevalence of thyroid autoantibodies in celiac and rheumatoid arthritis patients	Thyroid microsomal antibodies action on a section of microsome in the thyroid cell initiating inflammatory and cytotoxic effects on the thyroid follicle. Recommend investigation of gluten intolerance if elevated Anti-TPO.	Titer <9 IU/mL Anti-TPO often tested in conjunction with Anti-TG test.
<b>XI. Tests for Metabolic Disease</b>			
Amino acidurias	Dietary treatment is the major therapy for many of these genetic diseases: phenylketonuria, cystinuria, maple syrup urine disease, tyrosinemia, homocystinuria, Hartnup disease. See Chapter 44.	Monitoring amino acid level in urine or serum is necessary to assess adequacy of treatment.	Examples: Phe: 2-6 g/L (120-360 mmol/L) Phe (during pregnancy): 2-6 mg/dL (120-360 mmol/L) Cys: 2-22 g/L (10-90 mmol/L) Val: 17-37 g/L (145-315 mmol/L) Tyr: 4-16 g/L (20-90 mmol/L) (see particular lab references)
Organic Acids Panel	Urine or plasma amino acid testing; home collection of 10 ml sample of nocturnal and first morning urine, frozen, shipped to lab. <sup>9</sup>	Sensitive, broad range test that evaluates comprehensive functional markers for metabolic nutrient pathway functions that can suggest early markers for risk of disease or metabolic imbalances.	Excellent for overview of metabolic function and non-invasive pediatric testing.
<b>Diabetes Mellitus (See Chapter 31)</b>			
Prediabetes diagnosis	FBG: 100-125 mg/dL (impaired fasting glucose)	Prediabetes, blood glucose levels are higher than normal but not high enough for a diagnosis of diabetes.	Nondiabetic FBG = < 99 mg/dL
		American Diabetes Association recommends testing for prediabetes in adults without symptoms who are overweight or obese, and one or more additional risk factors for diabetes.	

Continued

## APPENDIX 30. Laboratory Values for Nutritional Assessment and Monitoring—cont'd

Test	Principles	Interpretation	Reference Range	Limitations and Implications
Diabetes diagnosis	1. Serum or whole blood glucose: after fasting 8–16 hours or on a casual blood sample.  2. Glucose tolerance test (GGT); 75 g glucose (100 g during pregnancy) given after fasting; serum glucose measured by before and five times during the next 3 hours after oral dosing.  Glucose measured by automated chemistry procedure.	1. Two or more fasting levels FBG >126 mg/dL are diagnostic; casual level >200 mg/dL followed by fasting level >126 mg/dL are diagnostic. Fasting levels of 110 to 126 mg/dL indicate IGT.  2. Serum levels FBG >200 mg/dL at 2-hour point is diagnostic; 2-hour level <140 and all 0- to 2-hour levels <200 are normal; 140–199 at 2 hours indicates IGT. Gestational diabetes: fasting >105; 1-hour GGT >190; 2 hour GGT >165; and 3-hour GGT >145 mg/dL.	2. Serum: Fasting: <110 mg/dL (<6.1 mmol/L) 30 min: >200 mg/dL (<11.1 mmol/L) 1 hour: <200 mg/dL (<11.1 mmol/L) 2 hours: <140 mg/dL (<7.8 mmol/L) 3 hours: 70–115 mg/dL (<6.4 mmol/L) 4 hours: 70–115 mg/dL (<6.4 mmol/L)  Urine: glucose negative	1. Elevated glucose levels are normal in physiologic stress; whole blood gives slightly lower values.  2. Often used for confirmation; ambulatory patient only; bed rest or stress impairs GGT; inadequate carbohydrate consumption before test invalidates results.
Diabetes monitoring	1. Blood glucose—monitoring requires that <i>the patient</i> monitor blood glucose level.  2. Serum fructosamine—assesses medium-term glucose control by measured glycated serum proteins; currently testing available in the laboratory and home tests.  3. Serum glycated hemoglobin or HgbA1C—assesses longer-term glucose control.  4. Porphyrin urine or whole blood testing for dioxin, <sup>31</sup> a toxin with significant association with promoting diabetes	1. Tight diabetes control requires frequent monitoring of glucose levels.  2. Allows assessment of average glucose levels for previous 2–3 weeks.  3. Allows assessment of average glucose levels for previous 2–3 months and verification of patient's serum glucose log.	1. 70–99 mg/dL (3.9–5.5 mmol/L)  2. Normal levels: 1%–2% of total protein Ranges vary according to method used.  3. Normal levels: Nondiabetic: 4.5–9% Good diabetic control: 4–7% Fair diabetic control: 6%–8% Poor diabetic control: >8%; Mean blood sugar 205 mg/dL or greater is associated with increased risk of side effects	A combination of glucose monitoring (by patient) and laboratory measurement of glycated proteins are needed to effectively monitor glucose control; fructosamine must be interpreted in light of plasma protein half-lives, and HgbA1C must be interpreted in light of RBC half-life.  Department of Defense study (July 2005) 47 percent increase in diabetes among veterans with the highest levels of dioxin. <sup>31</sup>

- <sup>a</sup>Factor = 5.95 for TPN; reflects severity of metabolic stress.
- <sup>b</sup>Red blood cells are separated from plasma by centrifugation and washed with saline; after hemolyzing the cells, the intracellular material is analyzed for vitamin availability.
- <sup>c</sup>No biochemical tests have been developed to assess B<sub>1</sub> status; the fraction of whole blood niacin as NAD is a potentially useful test (see Powers HJ). Current knowledge concerning optimum nutritional status of riboflavin, niacin, and pyridoxine, *Proc Nutr Soc* 58:435, 1999.
- <sup>d</sup>ALT and GPT are the same enzyme; AST and GOT are the same enzyme.
- <sup>e</sup>PLP is a rate-limiting co-enzyme in the transamination of amino acids (ALT and AST). PLP found primarily in liver and muscles.
- <sup>f</sup>Microbiologic growth assays, the deoxyuridine suppression test, and recently developed research tests for folate and vitamin B<sub>12</sub> are not generally offered in the contemporary clinical laboratory.
- <sup>g</sup>More sensitive procedures for measurement of vitamin K include serum chromatography and determination of the serum level of vitamin K-dependent bone protein called osteocalcin. Deficiency significantly increases the amount of abnormal forms of this protein. These tests are not yet widely available.
- <sup>h</sup>These substances are measured by similar techniques when the concentration in urine or other body fluids is determined.
- <sup>i</sup>These tests are combined with serum glucose, creatinine, and BUN on a test battery or panel. This set of tests is among the first and most frequently administered laboratory tests.
- <sup>j</sup>The CBC includes the red cell count, the red cell indices, Hb concentration, Hct, MCV, mean cell hemoglobin (MCH), mean cell hemoglobin concentration (MCHC), and white cell and platelet counts. Only Hct, Hb, and MCV are discussed here (see Savage RA: The red cell indices: yesterday, today, and tomorrow, *Clin Lab Med* 13:773-785, 1993).
- <sup>k</sup>Ranges are for adult men and premenopausal women. Pregnant women, infants, and children have different reference ranges.
- <sup>l</sup>See van Zeben D et al: Evaluation of microcytosis using serum ferritin and red cell distribution width, *Eur J Haematol* 44:106-109, 1990.
- <sup>m</sup>Taste acuity tests can be used to supplement laboratory methods (see, e.g., Gibson RS et al: A growth limiting mild zinc deficiency syndrome in some Southern Ontario boys with low growth percentiles, *Am J Clin Nutr* 49:1266, 1989).

**APPENDIX 31. Nutritional Implications of Selected Drugs**  
Sr. Jeanne P. Crowe, PharmD, RPh, RPI

Drug	Category	Drug Effect	Nutritional Implications and Cautions
<b>Selected Antiinfective Agents</b>			
Penicillins	Antibacterial agents	Long-term use may lead to oral candidiasis, diarrhea, epigastric distress. Some products contain high amounts of potassium or sodium.  May cause <i>Clostridium difficile</i> pseudomembranous colitis.	Use caution with low-sodium diet or potassium supplements. Take most oral forms 1 hour before or 2 hours after food to improve absorption. Take amoxicillin/potassium clavulanate with food to decrease GI distress. Focus on fluid and electrolyte replacement for diarrhea.
<b>Selected Macrolides</b>			
Azithromycin (Zithromax) Clarithromycin (Biaxin) Erythromycin (Ery-Tab)	Macrolide antibacterial agent Macrolide antibacterial agent Macrolide antibacterial agent	May cause GI distress, anorexia, stomatitis, bad taste in the mouth, or diarrhea. May increase sedative effect of alcohol.  May cause <i>Clostridium difficile</i> pseudomembranous colitis.	Take with food to decrease GI distress. Eat frequent, small, appealing meals to counteract anorexia. Use mouth rinses, sugarless gum, or lemon water for abnormal taste in mouth. Focus on fluid and electrolyte replacement for diarrhea. Avoid alcohol.
Sulfamethoxazole/ trimethoprim (Bactrim, Bactrim DS)	Sulfonamide combination antibacterial agent	May interfere with folate metabolism, especially with long-term use. May cause stomatitis, anorexia, nausea and vomiting, severe allergic reactions.  May cause <i>Clostridium difficile</i> pseudomembranous colitis.	Take with food and 8 oz of fluid to lessen nausea, vomiting, and anorexia. Folate supplement may be necessary. Discontinue drug and consult physician at first sign of allergic reaction.  Focus on fluid and electrolyte replacement for diarrhea.
<b>Selected Cephalosporins</b>			
Cephalexin (Keflex) Cefprozil (Ceftil) Cefuroxime axetil (Ceftin)	Cephalosporin antibacterial agent Cephalosporin antibacterial agent Cephalosporin antibacterial agent	May cause stomatitis, sore mouth and tongue and interfere with eating. May cause diarrhea.  May cause <i>Clostridium difficile</i> pseudomembranous colitis. Food increases bioavailability of tablets and suspension. Antacids, calcium, and magnesium supplements may decrease bioavailability.	Focus on fluid and electrolyte replacement for diarrhea. Eat moist, soft, low-salt foods as well as cold foods such as ice chips, sherbet, and yogurt for stomatitis and sore mouth. Take with a meal for optimal bioavailability. Take separately from antacids, calcium, or magnesium supplements
<b>Selected Fluoroquinolones</b>			
Ciprofloxacin (Cipro) Levofloxacin (Levaquin) Gatifloxacin (Tequin) Moxifloxacin (Avelox)	Fluoroquinolone antibacterial agents	Drug may rarely precipitate in renal tubules. Drug will bind to magnesium, calcium, zinc, and iron, forming an insoluble, unabsorbable complex.  Ciprofloxacin inhibits the metabolism of caffeine, causing increased central nervous system stimulation.  May cause <i>Clostridium difficile</i> pseudomembranous colitis.	Take drug with 8 oz of fluid; maintain adequate fluid intake. Limit caffeine intake. Take drug at least 2 hours before or 6 hours after antacids, magnesium, calcium, iron, or zinc supplements or multivitamin with minerals. Focus on fluid and electrolyte replacement for diarrhea.
<b>Selected Antimicrobial Agents</b>			
Linezolid (Zyvox)	Oxazolidinone antibacterial agent	Drug exhibits mild monoamine oxidase inhibition.  May cause taste change, oral candidiasis, and pseudomembranous colitis.	Avoid significant amounts (>100 mg) of high tyramine/pressor foods. See chart in 16th edition of <i>Food Medication Interactions</i> . Eat multiple small meals of appealing foods if taste changes become a problem. Focus on fluid and electrolyte replacement for diarrhea.

Tetracycline (Sumycin)	Antibacterial agent	Drug may cause anorexia. Drug will bind to $Mg^{2+}$ , $Ca^{2+}$ , $Zn^{2+}$ , and $Fe^{2+}$ , forming an insoluble unabsorbable complex. May decrease bacterial production of vitamin K in intestinal tract. May cause vitamin B deficiency with long-term use. Drug combined with vitamin A may increase the risk of benign intracranial hypertension.	Take supplements separately by 3 hours. Eat frequent, small, appealing meals to decrease anorexia. Avoid excessive vitamin A while taking drug. Vitamins K and B supplements may be necessary with long-term use. Focus on fluid and electrolyte replacement for diarrhea.
Metronidazole (Flagyl)	Antibacterial agent/antiprotozoal agent	May cause <i>Clostridium difficile</i> pseudomembranous colitis.	Take with food to avoid GI distress. Eat frequent, small, appealing meals to decrease anorexia. Avoid all alcohol during use and for 3 days after discontinuation.
Nitrofurantoin (Macrobid)	Nitrofuran Antibacterial agent	May cause anorexia, GI distress, stomatitis, and metallic taste in mouth. May cause disulfiram-like reaction when ingested with alcohol.	Drug should be taken with adequate calories, protein, and vitamin B complex. Avoid in G-6-PD deficiency because of increased risk of hemolytic anemia.
Gentamicin (Garamycin) Amikacin (Amikin)	Aminoglycoside Antibacterial agent Aminoglycoside Antibacterial agent Aminoglycoside Antibacterial agent	Drug may cause peripheral neuropathy, muscle weakness, and muscle wasting, especially in individuals with preexisting anemia, vitamin B deficiency, and electrolyte abnormalities. May cause <i>Clostridium difficile</i> pseudomembranous colitis. Drug may be ototoxic and nephrotoxic. Dehydration increases risk of toxicity.	Focus on fluid and electrolyte replacement for diarrhea. Adequate fluid intake and hydration necessary to lower risk of toxicity.
Isoniazid (Nydrazid)	Antitubercular agent	Drug may cause pyridoxine (vitamin $B_6$ ) and niacin (vitamin $B_3$ ) deficiency resulting in peripheral neuropathy and pellagra. Drug may affect vitamin D metabolism and decrease calcium and phosphate absorption. Drug processes MAO inhibitor-like activity.	Avoid use in malnourished individuals and others at increased risk for peripheral neuropathy. Supplement with 25 to 50 mg of pyridoxine and possibly B-complex if skin changes occur. Avoid foods high in tyramine (e.g., aged cheeses). Maintain adequate calcium and vitamin D intake. May need vitamin D supplement with long-term use.
Rifampin (Rifadin)	Antitubercular agent	Drug may increase metabolism of vitamin D. Rare cases of osteomalacia have been reported.	Increase intake of foods high in copper and zinc; take daily multivitamin with minerals when drug is used long term.
Ethambutol (Myambutol)	Antitubercular agent	Drug may decrease body copper and zinc.	Maintain adequate hydration and purine-restricted diet.
Pyrazinamide	Antitubercular agent	Drug may decrease the excretion of uric acid, leading to hyperuricemia and gout. Drug may decrease the excretion of uric acid, leading to hyperuricemia and gout.	Maintain adequate hydration and purine-restricted diet.
<b>Selected Antifungal Agents</b>			
Amphotericin B (Fungizone) Ketoconazole (Nizoral)	Antifungal agent Antifungal agent	Drug may cause anorexia and weight loss. Drug causes loss of potassium, magnesium, and calcium. Drug does not dissolve at pH >5.	Eat frequent, small, appealing meals high in magnesium, potassium, calcium. Ensure adequate hydration. Take with food to increase absorption. Take with acidic liquid (e.g., cola), especially individuals with achlorhydria.
<b>Hematologic Agents</b>			
Warfarin (Coumadin)	Anticoagulant	Prevents the conversion of oxidized vitamin K to the active form. Produces a state of systemic anticoagulation. May inhibit mineralization of newly formed bone.	Consistent intake of dietary supplements (i.e., in vitamins) must be consistent to achieve desired state of anticoagulation. Monitor bone mineral density in individuals on long-term therapy.
Aspirin (Bayer Ecotrin)	Salicylate platelet inhibitor	Drug may cause GI irritation and bleeding. Drug may decrease uptake of vitamin C by leukocytes and increase urinary loss; decreases systemic levels of iron, folic acid, sodium, and potassium, especially with high dose and long-term use.	Incorporate foods high in vitamin C and folic acid into diet. Monitor electrolytes, hemoglobin to determine need for potassium or iron supplements. Avoid alcohol consumption. See new recommendation for use of low dose aspirin (81 mg) in 16th edition of <i>Food and Medication Interaction</i> .

Continued

## APPENDIX 31. Nutritional Implications of Selected Drugs—cont'd

Drug	Category	Drug Effect	Nutritional Implications and Cautions
<b>Hormonal and Metabolic Agents</b>			
Metformin (Glucophage)	Biguanide	Drug may decrease absorption of vitamin B <sub>12</sub> , folic acid. May cause lactic acidosis.	Maintain prescribed diabetic diet. Increase foods high in vitamin B <sub>12</sub> and folic acid or supplement if necessary. Avoid alcohol to decrease risk of lactic acidosis.
Prednisone Methylprednisolone (Medrol)	Corticosteroid Corticosteroid	Drug induces protein catabolism, resulting in muscle wasting, atrophy of bone protein matrix, delayed wound healing. Drug decreases intestinal absorption of calcium; promotes urinary loss of calcium, potassium, zinc, vitamin C, nitrogen; causes sodium retention.	Maintain diet high in calcium, vitamin D, protein, potassium, zinc, and vitamin C, and low in sodium. Calcium and vitamin D supplements recommended for prevention of osteoporosis with long-term use of drug.
Alendronate (Fosamax) Risedronate (Actone) Ibandronate (Boniva)	Bisphosphonates	Drug may induce mild decrease in serum calcium.	Diet high in calcium or calcium and vitamin D supplement. Drug must be taken 30 minutes (alendronate and risedronate) or 1 hour (ibandronate) before first food or medication of the day on completely empty stomach with plain water only.
Oxandrolone (Oxandrin)	Anabolic steroid	Drug is used to promote weight gain and muscle mass after surgery, trauma, infection. May increase blood glucose and lipids.	Drug must consist of adequate calories and protein to promote anabolic effect. Monitor weight, blood glucose, lipids, and hepatic function.
Estrogen (Premarin) Oral contraceptives	Sex hormones	Drug may decrease absorption and tissue uptake of vitamin C. Drug may increase absorption of vitamin A. May inhibit folate conjugate and decrease serum folic acid levels. Drug may decrease serum levels vitamin B <sub>6</sub> , B <sub>12</sub> , riboflavin, magnesium, zinc.	Maintain diet with adequate magnesium, folic acid, vitamin B <sub>6</sub> and B <sub>12</sub> , riboflavin, and zinc. Calcium and vitamin D supplements may be recommended with estrogen as hormone replacement for postmenopausal women.
<b>Cardiovascular Agents</b>			
Digoxin (Lanoxin)	Cardiac glycoside	Drug may increase urinary loss of magnesium and decrease serum levels of potassium.	Hypokalemia, hypomagnesemia, and hypercalcemia increase drug toxicity. Maintain diet high in potassium and magnesium. Caution with calcium supplements and antacids.
Propranolol (Inderal LA, InnoPran LA) Metoprolol (Lopressor, Toprol XL)	β-Adrenergic antagonist β-Adrenergic antagonist β-Adrenergic antagonist	Drug may mask sympathetic signs of hypoglycemia. Drug may prolong hypoglycemia. Drug may decrease insulin release in response to hypoglycemia.	Maintain prescribed diabetic diet. Monitor blood glucose for hyperglycemia. Monitor for nonsympathetic signs of hypoglycemia.
Atenolol (Tenormin) Benzapril (Lotensin) Enalapril (Vasotec) Fosinopril (Monopril) Lisinopril (Zestril, Prinivil) Candesartan (Atacand) Irbesartan (Avapro) Losartan (Cozaar) Olmesartan (Benicar) Telmisartan (Micardis) Valsartan (Diovan)	ACE inhibitor ACE inhibitor ACE inhibitor ACE inhibitor Angiotensin II receptor antagonist Angiotensin II receptor antagonist	Drug may increase serum potassium levels.  Drug may increase serum potassium levels.	Caution with high potassium diet or potassium supplements. Avoid salt substitutes. Ensure adequate fluid intake and hydration. Check recommendation for each agent as regards ingestion with food. See monograph in 16th edition of <i>Food Medication Interactions</i> .  Caution with high-potassium diet or potassium supplements. Avoid salt substitutes. Ensure adequate fluid intake and hydration. Avoid natural licorice. Avoid grapefruit and related citrus with losartan.

Clonidine (Catapres)	Alpha-adrenergic agonist	Drug commonly causes dizziness, drowsiness, sedation.	Avoid alcohol and alcohol products. Drug increases sensitivity to alcohol, which may increase sedation caused by drug alone.
Hydralazine (Apresoline)	Peripheral vasodilator	Drug interferes with pyridoxine (vitamin B <sub>6</sub> ) metabolism. May result in pyridoxine deficiency.	Maintain a diet high in pyridoxine. Supplementation may be necessary.
Quinidine (Quinaglute)	Antiarrhythmic agent	Cardiac toxicity of drug is increased in the presence of hypokalemia, hypomagnesemia, and hypocalemia.	Provide diet adequate in potassium, magnesium, calcium to maintain normal serum levels. Supplementation may be necessary.
<b>Antihyperlipidemic Agents</b>			
Atorvastatin (Lipitor)	HMG Co-A reductase inhibitor	Drug may cause significant reduction in coenzyme Q <sub>10</sub> . Drug lowers low-density lipoprotein- cholesterol; raises high-density lipoprotein cholesterol.	Supplementation with coenzyme Q <sub>10</sub> is controversial. Drug is adjunct to diet therapy. Maintain low-fat, low-cholesterol diet for optimal drug effect. Avoid grapefruit and related citrus with atorvastatin, lovastatin, or simvastatin.
Fluvastatin (Lescol)	HMG Co-A reductase inhibitor		
Lovastatin (Mevacor)	HMG Co-A reductase inhibitor		
Pravastatin (Pravachol)	HMG Co-A reductase inhibitor		
Rosuvastatin (Crestor)	HMG Co-A reductase inhibitor		
Simvastatin (Zocor)	HMG Co-A reductase inhibitor		
Gemfibrozil (Lopid)	Fibric acid derivative	Drug decreases serum triglycerides.	Maintain low-fat, low-sucrose diet; avoid alcohol for optimal therapeutic effect.
Fenofibrate (Tricor)	Fibric acid derivative	Drug binds fat-soluble vitamins (A, E, D, K), β-carotene, calcium, magnesium, iron, zinc, and folic acid.	Take fat-soluble vitamins in water-miscible form or take vitamin supplement at least 1 hour before first dose of drug daily. Maintain diet high in folic acid, magnesium, calcium, iron, zinc, or supplements when necessary.
Cholestyramine (Questran)	Bile acid sequestrant		Monitor serum nutrient levels with long-term use of drug.
Niacin (Niaspan)	Nicotinic acid	High dose may elevate blood glucose and uric acid.	Maintain diabetic, low-purine diet if necessary.
<b>Diuretics</b>			
Eurosemide (Lasix)	Loop diuretic	Drug increases urinary excretion of sodium, potassium, magnesium, calcium.	Maintain diet high in potassium, magnesium, and calcium. Avoid natural licorice, which may counteract the diuretic effect of the drug. Monitor electrolytes; supplementation may be necessary.
Bumetanide (Bumex)	Loop diuretic		
Hydrochlorothiazide (HydroDIURIL)	Thiazide diuretic	Drug increases urinary excretion of sodium, potassium, magnesium. Drug increases renal resorption of calcium.	Maintain diet high in potassium and magnesium. Avoid natural licorice, which may counteract the diuretic effect of the drug. Monitor electrolytes; supplementation may be necessary. Use caution with calcium supplements.
Triamterene (Dyrenium)	Thiazide diuretic	Drug increases renal resorption of potassium.	Avoid salt substitutes. Use caution with potassium supplements. Avoid excessive potassium intake in diet.
Spiromebolactone (Aldactone)	Potassium-sparing diuretic		
<b>Analgesics</b>			
Aceraminophen (Tylenol)		Drug may cause hepatotoxicity at high dose. Chronic alcohol ingestion increases the risk of hepatotoxicity.	Maximum safe adult dose is <4 g/day. Avoid alcohol or limit to <2 drinks/day.
NSAIDs such as ibuprofen (Motrin), naproxen (Naprosyn), meloxicam (Mobic)		<b>Standard warning with all NSAIDs:</b>	Take drug with food or milk to decrease risk of GI toxicity.
		<b>GI:</b> NSAIDs cause an increased risk of serious GI adverse events, including bleeding, ulceration, and perforation of the stomach and intestines, which can be fatal. These events can occur at anytime during use and without prior symptoms. The elderly are at greater risk for serious GI events.	Avoid use in the elderly.
			Avoid use in individuals with severe cardiovascular disease.
		<b>Cardiovascular:</b> NSAIDs may cause increased risk of serious cardiovascular thrombotic events, myocardial infarction, and stroke, which can be fatal.	

**APPENDIX 31. Nutritional Implications of Selected Drugs—cont'd**

Drug	Category	Drug Effect	Nutritional Implications and Cautions
<b>Selected Narcotic Analgesics</b>			
Morphine (MS Contin, Avinza)	Narcotic analgesic	All narcotics may cause dose-related sedation, respiratory depression, dry mouth, constipation. May be severe.	Monitor respiratory function and bowel function (not with paralytic ileus).
Oxycodone (OxyContin)	Narcotic analgesic	Heat causes faster absorption of transdermal fentanyl.	Do not crush or chew sustained-released formulas.
Fentanyl (Duragesic, Onsolis)	Narcotic analgesic		Do not use with heating pad, hot tub, sunbathing. Use caution with high fever.
<b>Antidepressants</b>			
Fluoxetine (Prozac)	Selective serotonin reuptake inhibitor	Fluoxetine may cause anorexia and weight loss. Fluoxetine may decrease the absorption of leucine. Some herbal and natural products may increase toxicity.	Avoid tryptophan, St. John's wort.
Paroxetine (Paxil)	Selective serotonin reuptake inhibitor		Additive effects may produce adverse effects or serotonin syndrome.
Sertraline (Zoloft)	Selective serotonin reuptake inhibitor		Monitor caloric intake. Maintain consistent amount of fiber in diet.
Trazodone (Desyrel)	Unclassified antidepressant	Some herbal and natural products may increase toxicity.	Avoid foods high in tyramine during drug use and for 2 weeks after discontinuation to prevent hypertensive crisis.
Venlafaxine (Effexor XR)	Unclassified antidepressant	Mirtazapine may cause significant increase in appetite and weight gain.	Monitor caloric intake to avoid weight gain.
Mirtazapine (Remeron)	Unclassified antidepressant		Drink 2 to 3 L of fluid daily to avoid dehydration. Maintain consistent dietary sodium intake. Take with food to decrease GI irritation.
Amitriptyline (Elavil)	Triyclic antidepressant	Drug may cause increased appetite (especially for carbohydrates and sweets) and weight gain. High fiber may decrease drug absorption.	
Phenelzine (Nardil)	MAO inhibitor	Drug may cause increased appetite (especially for carbohydrates and sweets) and weight gain. Risk for severe reaction with dietary tyramine.	
Lithium carbonate (Lithobid)	Antimanic and antidepressant	Sodium intake affects drug levels. Low-sodium diet, dehydration, increased drug toxicity. Drug may cause GI irritation.	
<b>Antipsychotic Agents</b>			
Clozapine (Clozaril)	Second generation antipsychotic	Drug may cause increased appetite and weight gain. Drug may cause life-threatening toxic agranulocytosis.	Monitor for weight gain and calorie count. Individual must be enrolled in and adhere to requirements of Clozaril program, including a weekly white blood cell count.
Olanzapine (Zyprexa)	Second generation antipsychotics	Drugs may cause increased appetite and weight gain.	Monitor weight and food intake. Monitor fasting blood sugar and HbA1c. Monitor lipids and triglycerides.
Risperidone (Risperdal)		May cause increased blood sugar and HbA1c. May increase lipids and triglycerides.	Do not use in elderly dementia patients. May increase risk of stroke.
Quetiapine (Seroquel)			Closer monitoring of blood glucose in the diagnosed diabetic individual. Periodic check of blood glucose in the "at-risk" nondiabetic individual. Monitor weight and calorie count.
Chlorpromazine (Thorazine)	First-generation antipsychotic, low potency	Drug may impair glucose tolerance and insulin release. May cause increased appetite and weight gain.	Tardive dyskinesia may interfere with biting, chewing, swallowing.
Haloperidol (Haldol)	First-generation antipsychotic, high potency	Risk for tardive dyskinesia.	Monitor weight and calorie count. Tardive dyskinesia may interfere with biting, chewing, swallowing.

<b>Antianxiety and Hypnotic Agents</b>			
Lorazepam (Ativan)	Benzodiazepine	Drugs may cause significant sedation.	Avoid concurrent ingestion of alcohol, which will produce CNS depression. Limit or avoid caffeine, which may decrease the therapeutic effect of the drug. Use caution with herbal and natural products that cause CNS stimulation or sedation.
Diazepam (Valium)	Benzodiazepine		
Alprazolam (Xanax)	Benzodiazepine		
Clonazepam (Klonopin)	Benzodiazepine		
Temazepam (Restoril)	Benzodiazepine hypnotic		
Zolpidem (Ambien)	Nonbenzodiazepine hypnotic		
<b>Selected Anticonvulsant Agents</b>			
Carbamazepine (Tegretol)		Drug may decrease biotin, folic acid, and vitamin D levels.	Maintain diet high in folic acid and vitamin D. Calcium and vitamin D supplementation may be necessary for long-term therapy to prevent loss of bone mineral density.
Phenytoin (Dilantin)	Hydantoin	Drug may decrease serum levels of folic acid, calcium, vitamin D, biotin, and thiamin.	Folic acid, calcium, and vitamin D supplement may be recommended with long-term use.
Phenobarbital	Barbiturate	Drug may induce rapid metabolism of vitamin D and produce deficiency of vitamin D and calcium. Drug may increase the metabolism of vitamin K, decrease serum folic acid and vitamin B <sub>12</sub> levels.	Increase dietary intake of calcium, vitamin D, and folic acid. May need calcium, vitamin D, folic acid, and vitamin B <sub>12</sub> supplementation with long-term use of drug.
Lamotrigine (Lamictal)	Anticonvulsant and adjunct mood stabilizer in bipolar disorder	Dose must be titrated slowly to avoid rash which may be fatal. Increased incidence of rash in children	Avoid alcohol. Monitor renal and hepatic function. Monitor for rash. Monitor renal and hepatic function.
Lacosamide (Vimpat)		Drug may cause dizziness, ataxia, dry mouth, nausea and vomiting.	May cause hepatotoxicity. Do not use in individual with mild hepatic dysfunction. Monitor hepatic function.
<b>Anti-Alzheimer's Agents</b>			
Donepezil (Aricept)	Cholinesterase inhibitor	Drug is highly cholinergic; may cause anorexia, nausea and vomiting, diarrhea, increased gastric acid secretion, GI bleeding.	Take drug with food to prevent GI irritation. Monitor food intake and weight.
Rivastigmine (Exelon)	Cholinesterase inhibitor		Avoid diet that alkalinizes the urine to avoid drug toxicity.
Galantamine (Razadyne)	Cholinesterase inhibitor		
Memantine (Namenda)	NMDA receptor antagonist	Drug is cleared from the body almost exclusively by renal excretion. Urine pH >8 decreases renal excretion by 80%.	
<b>Gastrointestinal Agents</b>			
Famotidine (Pepcid)	H <sub>2</sub> receptor antagonist	Drug may reduce the absorption of vitamin B <sub>12</sub> and iron.	Monitor iron studies, vitamin B <sub>12</sub> level while on long-term therapy. Supplement if necessary.
Nizatidine (Axid)	H <sub>2</sub> receptor antagonist		
Ranitidine (Zantac)	Proton pump inhibitor	Inhibition of acid secretion may inhibit the absorption of iron and vitamin B <sub>12</sub> .	Monitor iron studies and vitamin B <sub>12</sub> levels with long-term use of drug. Supplement if necessary.
Omeprazole (Prilosec)	Proton pump inhibitor	Long-term calcium absorption leading to osteoporosis.	Monitor bone density with long-term use.
Lansoprazole (Prevacid)	Proton pump inhibitor	Long-term inhibition of acid secretion may increase the risk of <i>Clostridium difficile</i> pseudomembranous colitis.	Monitor blood glucose in persons with diabetes carefully when drug is initiated. Avoid alcohol. Tardive dyskinesia may interfere with biting, chewing, swallowing.
Pantoprazole (Protonix)	Proton pump inhibitor		
Rabeprazole (AcipHex)	Proton pump inhibitor		
Dexlansoprazole	Proton pump inhibitor		
Metoclopramide (Reglan)	Prokinetic agent		

Continued

## APPENDIX 31. Nutritional Implications of Selected Drugs—cont'd

Drug	Category	Drug Effect	Nutritional Implications and Cautions
<b>Selected Antineoplastic Agents</b>			
Methotrexate	Folate antagonist	Drug inhibits dihydrofolate reductase; decreased formation of active folate. Drug may cause GI irritation or injury.	Maintain diet high in folic acid and vitamin B <sub>12</sub> . Daily folic acid supplement recommended with antirheumatic doses. Leucovorin rescue may be necessary with antineoplastic doses.
Cyclophosphamide (Cytoxan) All antineoplastic agents	Alkylating agent	Drug metabolite causes bladder irritation, acute hemorrhagic cystitis. All agents are cytotoxic; potential to damage intestinal mucosal.	Maintain high fluid intake (2–3 L daily) to induce frequent voiding. Extensive effects discussed in Chapter 16.
<b>Selected Anti-Parkinson Agents</b>			
Carbidopa/levodopa (Sinemet)	Dopamine precursor	Carbidopa protects levodopa against pyridoxine-enhanced peripheral decarboxylation to dopamine.	Pyridoxine supplements in excess of 10–25 mg daily may increase carbidopa requirements and increase adverse effects of levodopa.
Bromocriptine (Parlodel)	Dopamine agonist	Drug may cause GI irritation, nausea, vomiting, and GI bleeding.	Take drug with food to prevent GI irritation. Take drug at bedtime to decrease nausea.
Selegiline (Edepryl)	MAO-B inhibitor	Drug selectively inhibits MAO-B at 10 mg or less per day. Drug loses selectivity at higher doses.	Avoid high-tyramine foods at doses greater than 10 mg/day.
Entacapone (Comtan)	COMT inhibitor	Drug chelates iron; may decrease serum iron levels.	May precipitate hypertension. Take iron supplement separately from drug.
<b>CNS Stimulants</b>			
Methylphenidate (Ritalin, Concerta)	CNS stimulant	Drug may cause anorexia, weight loss, and decreased growth.	Ensure adequate calorie intake. Limit ingestion of caffeine; avoid alcohol and herbal products. Monitor children's weight and growth.
Amphetamine (Adderall, Dexedrine)	CNS stimulant	Drug may cause anorexia, decreased weight loss, and decreased growth.	Ensure adequate calorie intake. Limit ingestion of caffeine; avoid alcohol and herbal products. High-dose vitamin C may decrease drug absorption, increase drug excretion, and decrease half-life of drug. Monitor children's weight and growth.
<b>Miscellaneous</b>			
Sapropterin (Kuvan)	Hyper – PKU treatment Enzyme enhancer in BH4 responsive PKU	Patient must have sufficient residual PAH.	Take with food to increase absorption. Drug is an adjunct to low phenylalanine diet. Monitor phenylalanine level.

## APPENDIX 32. Enteral Formulas and Their Indications for Use

General information on formula types and their use is presented here. For more detailed information on formulas consult: Abbott Nutrition, [www.abbottnutrition.com](http://www.abbottnutrition.com) and Nestlé Nutrition, [www.nestle-nutrition.com](http://www.nestle-nutrition.com).

<b>Enteral Formulas</b>	<b>kcal/mL</b>	<b>Protein (g/L)</b>	<b>CHO (g/L)</b>	<b>Fat (g/L)</b>	<b>mOsm</b>	<b>Free H<sub>2</sub>O (mL/L)</b>	<b>Notes</b>
Standard	1-1.2	44-53	144-160	35-39	300-450	800-1260	For patients without malabsorption, hypermetabolism, or major organ failure; available with or without fiber
Calorie-dense	1.5	63-68	170-203	49-65	525-650	762-778	For patients requiring less volume; available with or without fiber
High-protein	1-1.2	53-63	130-160	26-39	340-490	818-839	For patients with healing needs or low kcal:protein needs; available with or without fiber
Renal	1.8-2	45-81	167-205	96-100	700-960	709-736	For patients with compromised renal function; formulas differ based on if patient is on dialysis or if diabetes present
Glucose-control	1-1.2	45-60	96-100	48-59	280-470	805-840	Low carbohydrate, high fat, fiber containing
*Peptide-based	1-1.5	40-68	127-188	39-56	380-585	771-832	Formulated to promote maximal intestinal absorption of protein; contains di- and tri-peptides from whey protein; increased MCT:LCT fat ratio; available with higher levels of protein
Critical Care	1.5	94	134-172	51-68	480-595	759-772	High calorie, high protein formulated to support immune function and support healing; increased omega-3 fat; some with fiber
Pulmonary	1.5	63-68	100-106	93-95	330-785	535-785	Low carbohydrate; aimed at decreasing respiratory quotient and decreasing inflammation
<b>Modular Additives</b>	<b>kcal</b>	<b>Protein (g)</b>	<b>CHO (g)</b>	<b>Fat (g)</b>			
Protein/100 g	357	6	0	0			Whey protein aimed at increasing protein content of food and formulas
Glucose/100 g	380	0	94	0			Glucose polymer powder for adding carbohydrate calories
Lipid/15 mL	68	0	0	7.5			Safflower oil for adding fat calories

\*Available in pediatric formulas

## APPENDIX 33. DASH Diet

The DASH diet is an eating pattern that reduces high blood pressure. It is not the traditional low-salt diet. DASH uses foods high in the minerals calcium, potassium, and magnesium, which, when combined, help lower blood pressure. It is also low in fat and high in fiber, an eating style recommended for everyone.

The Healthy Eating Pattern is the template for the DASH eating pattern, with inclusion of  $\frac{1}{2}$  to 1 serving of nuts, seeds, and legumes daily, limited fats and oils, and use of nonfat or low-fat milk. The eating pattern is reduced in saturated fat, total fat, cholesterol, and sweet and sugar-containing beverages; and provides abundant servings of fruits and vegetables.

Although the DASH eating plan is naturally lower in salt because of the emphasis on fruits and vegetables, all adults should still make an effort to reduce packaged and processed foods and high-sodium snacks (such as salted chips, pretzels, and crackers) and use less or no salt at the table.

DASH can be an excellent way to lose weight. Because weight loss can help lower blood pressure, it is often suggested. In addition to following DASH, try adding in daily physical activity such as walking or other exercise. You may want to check with your doctor first.

Current recommendations include:

### The Dash Diet

Food Group	1600 kcal Servings/Day	2000 kcal Servings/Day	2600 kcal Servings/Day	3100 kcal Servings/Day
Grains (whole grains)	6	7-8	10-11	12-13
Vegetables	3-4	4-5	5-6	6
Fruits and juices	4	4-5	5-6	6
Milk, nonfat or low-fat	2-3	2-3	3	3-4
Meats, poultry, and fish	1-2	2 or less	6	2-3
Nuts, seeds, and legumes	3/week	$\frac{1}{2}$ -1	1	1
Fats and oils	2	2-3	3	4
Sweets	0	5/week	Less than 2	2

### Dietary Guidelines

Food Group	Servings/Day	Serving Sizes	Examples	Significance of Each Food Group
Grains	6-13	1 slice bread $\frac{1}{2}$ cup (1 oz) dry cereal* $\frac{1}{2}$ cup cooked rice, pasta, or cereal and fiber	Whole-wheat bread, English muffin, pita bread, bagel, cereals, grits, oatmeal, crackers, unsalted pretzels, and popcorn	Major sources of energy
Vegetables	3-6	1 cup raw, leafy veg $\frac{1}{2}$ cup cooked veg 6 oz veg juice	Tomatoes, potatoes, carrots, peas, kale, squash, broccoli, turnip greens, collards, spinach, artichokes, beans, sweet potatoes	Rich sources of potassium, magnesium, antioxidants, and fiber
Fruits	4-6	6 oz fruit juice 1 medium fruit $\frac{1}{4}$ cup dried fruit $\frac{1}{2}$ cup fresh, frozen, or canned fruit	Apricots, bananas, dates, grapes, oranges and juice, tangerines, strawberries, mangoes, melons, peaches, pineapples, prunes, raisins, grapefruit and juice	Important sources of energy, potassium, magnesium, and fiber
Low-fat dairy	2-4	8 oz milk, 1 cup yogurt, or 1.5 oz cheese	Fat-free or 1% milk, fat-free or low-fat buttermilk, yogurt, or cheese	Major sources of calcium, vitamin D, and protein
Meat, poultry, fish	1-3	3 oz cooked meats, poultry, or fish 1 egg white†	Select only lean meats; trim away visible fats, broil, roast, boil, instead of frying; remove skin from poultry	Rich sources of protein, zinc, and magnesium
Nuts, seeds, legumes	3/wk-1/day	1.5 oz ( $\frac{1}{2}$ cup) nuts, $\frac{1}{2}$ oz or 2 tbsp seeds, $\frac{1}{2}$ cup cooked legumes	Almonds, filberts, mixed nuts, walnuts, sunflower seeds, kidney beans, lentils	Rich sources of energy, magnesium, protein, monounsaturated fats, and fiber
Fat	2-4	1 tsp soft margarine, veg oil, 1 Tbsp low-fat mayo or salad dressing, or 2 Tbsp light salad dressing‡	Soft margarine, low fat mayo, veg oil, light salad dressing	The DASH study had 27% of calories as fat, including fat in or added to foods Sweets should be low in fat

National Institutes of Health, National Heart, Lung, and Blood Institute: YOUR GUIDE TO Lowering Your Blood Pressure With DASH, U.S. Department of Health and Human Services, NIH Publication No. 06-4082, 2006.

\*Serving sizes vary between  $\frac{1}{2}$  cup and  $1\frac{1}{4}$  cup, depending on cereal type. Check the product's Nutrition Facts label.

†Because eggs are high in cholesterol, limit egg yolk intake to no more than four per week; two egg whites have the same protein content as 1 oz of meat.

‡Fat content changes serving amount for fats and oils. For example, 1 Tbsp of regular salad dressing equals one serving; 1 Tbsp of a low-fat dressing equals one-half serving; 1 Tbsp of a fat-free dressing equals zero servings.

## APPENDIX 33. DASH Diet—cont'd

### Sample Menu

Breakfast	Lunch	Dinner
1 cup calcium-fortified orange juice ¾ cup Raisin Bran 1 cup skim milk Mini –whole-wheat bagel 1½ tsp soft margarine 1 cup coffee 2 tsp sugar	3-oz boneless skinless chicken breast 2 slices reduced-fat cheese 2 large leaves lettuce 2 slices tomato 1 Tbsp light mayonnaise 2 slices whole wheat bread 1 medium apple ½ cup raw carrot sticks 1 cup iced tea	1 cup spaghetti with vegetarian/low-sodium tomato sauce 3 Tbsp Parmesan cheese ½ cup green beans 1 cup spinach, raw ½ cup mushrooms, raw 2 Tbsp croutons 2 Tbsp low-fat Italian dressing 1 slice Italian bread ½ cup frozen yogurt
<b>Midmorning Snack</b>	<b>Midafternoon Snack</b>	
1 cup apple juice 2 oz walnuts	1 large banana	
<b>Nutritional Analysis:</b>	Kilocalories: 1980 Protein: 78 g Fat: 56 g Saturated fat: 13 g Carbohydrates: 314 g	Sodium: 2377 mg Potassium: 4129 mg Fiber: 32 g Magnesium: 517 g

## APPENDIX 34. Exchange Lists for Meal Planning—cont'd

### How This Exchange List Works With Meal Planning

There are three main groups of foods in this exchange list. They are based on the three major nutrients: carbohydrates, protein (meat and meat substitutes), and fat. Each food list contains foods grouped together because they have similar nutrient content and serving sizes. Each serving of a food has about the same amount of carbohydrate, protein, fat, and calories as the other foods on the same list.

- Foods on the **Starch** list, **Fruits** list, **Milk** list, and **Sweets, Desserts, and Other Carbohydrates** list are similar because they contain 12 to 15 grams of carbohydrate per serving.
- Foods on the **Fat** list and **Meat and Meat Substitutes** list usually do not have carbohydrate (except for the plant-based meat substitutes such as beans and lentils).

- Foods on the Starchy Vegetables list (part of the **Starch** list and including foods such as potatoes, corn, and peas) contain 15 grams of carbohydrate per serving.
- Foods on the **Nonstarchy Vegetables** list (such as green beans, tomatoes, and carrots) contain 5 grams of carbohydrate per serving.
- Some foods have so little carbohydrate and calories that they are considered “free,” if eaten in small amounts. You can find these foods on the **Free Foods** list.
- Foods that have different amounts of carbohydrates and calories are listed as **Combination Foods** (such as lasagna) or **Fast Foods**. Foods are listed with their serving sizes, which are usually measured after cooking. When you begin, measuring the size of each serving will help you learn to “eyeball” correct serving sizes. The following chart shows the amount of nutrients in one serving from each list:

Food List	Carbohydrate (grams)	Protein (grams)	Fat (grams)	Calories
<b>Carbohydrates</b>				
Starch: breads, cereals and grains, starchy vegetables, crackers and snacks, and beans, peas, and lentils	15	0-3	0-1	80
Fruits	15	—	—	60
Milk				
Fat-free, low-fat, 1%	12	8	0-3	100
Reduced fat, 2%	12	8	5	120
Whole	12	8	8	160
Sweets, desserts, and other carbohydrates	15	Varies	Varies	Varies
Nonstarchy Vegetables	5	2	—	25
<b>Meat and Meat Substitutes</b>				
Lean	—	7	0-3	45
Medium-fat	—	7	4-7	75
High-fat	—	7	8+	100
Plant-based proteins	Varies	7	Varies	Varies
<b>Fats</b>				
Alcohol	Varies	—	—	100

### Starch

Cereals, grains, pasta, breads, crackers, snacks, starchy vegetables, and cooked beans, peas, and lentils are starches. In general, 1 starch is:

- ½ cup of cooked cereal, grain, or starchy vegetable
- ½ cup of cooked rice or pasta
- 1 oz of a bread product, such as 1 slice of bread
- ¾ oz to 1 oz of most snack foods (some snack foods may also have extra fat)

### Nutrition Tips

- A choice on the **Starch** list has 15 grams of carbohydrate, 0-3 grams of protein, 0-1 grams of fat, and 80 calories.
- For maximum health benefits, eat three or more servings of whole grains each day. A serving of whole grain is about ½ cup of cooked cereal or grain, 1 slice of whole-grain bread, or 1 cup of whole-grain cold breakfast cereal.

### Selection Tips

- Choose low-fat starches as often as you can.
- Starchy vegetables, baked goods, and grains prepared with fat count as 1 starch and 1 fat.
- For many starchy foods (bagels, muffins, dinner rolls, buns), a general rule of thumb is 1 oz equals 1 serving. Always check the size you eat. Because of their large size, some foods have a lot more carbohydrate (and calories) than you might think. For example, a large bagel may weigh 4 oz and equal 4 carbohydrate servings.
- For specific information, read the Nutrition Facts panel on the food label.

Food	Serving Size
<b>Bread</b>	
Bagel, large (about 4 oz)	¼ (1 oz)
Biscuit, 2½ inches across <sup>†</sup>	1
Bread	
Reduced-calorie*	2 slices (1½ oz)
White, whole-grain, pumpernickel, rye, unfrosted raisin	1 slice (1 oz)
Chapatti, small, 6 inches across	1
Cornbread, 1¼ inch cube <sup>†</sup>	1 (1½ oz)

Food	Serving Size
English muffin	½ (1 oz)
Hot dog bun or hamburger bun	½ (1 oz)
Naan, 8 inches by 2 inches	¼
Pancake, 4 inches across, ¼ inch thick	1
Pita, 6 inches across	½
Roll, plain, small	1 (1 oz)
Stuffing, bread <sup>†</sup>	½ cup
Taco shell, 5 inches across <sup>†</sup>	2
Tortilla, corn, 6 inches across	1

## APPENDIX 34. Exchange Lists for Meal Planning—cont'd

Food	Serving Size	Food	Serving Size
Tortilla, flour, 6 inches across	1	Potato	
Tortilla, flour, 10 inches across	$\frac{1}{3}$ tortilla	Baked with skin	$\frac{1}{4}$ large (3 oz)
Waffle, 4-inch square or 4 inches across <sup>†</sup>	1	Boiled, all kinds	$\frac{1}{2}$ cup or $\frac{1}{2}$ medium (3 oz)
<b>Cereals and Grains</b>		Mashed, with milk and fat <sup>†</sup>	$\frac{1}{2}$ cup
Barley, cooked	$\frac{1}{3}$ cup	French fried (oven-baked)	1 cup (2 oz)
Bran, dry		Pumpkin, canned, no sugar added*	1 cup
Oat*	$\frac{1}{4}$ cup	Spaghetti/pasta sauce	$\frac{1}{2}$ cup
Wheat*	$\frac{1}{2}$ cup	Squash, winter (acorn, butternut)*	1 cup
Bulgur (cooked)*	$\frac{1}{2}$ cup	Succotash*	$\frac{1}{2}$ cup
Cereals		Yam, sweet potato, plain	$\frac{1}{2}$ cup
Bran*	$\frac{1}{2}$ cup	<b>Crackers and Snacks</b>	
Cooked (oats, oatmeal)	$\frac{1}{2}$ cup	Animal crackers	8
Puffed	$1\frac{1}{2}$ cup	Crackers	
Shredded wheat, plain	$\frac{1}{2}$ cup	Round-butter type <sup>†</sup>	6
Sugar-coated	$\frac{1}{2}$ cup	Saltine-type	6
Unsweetened, ready-to-eat	$\frac{1}{4}$ cup	Sandwich-style, cheese or peanut butter filling <sup>†</sup>	3
Couscous	$\frac{1}{3}$ cup	Whole-wheat regular <sup>†</sup>	2-5 ( $\frac{1}{4}$ oz)
Granola		Whole-wheat lower fat or crispbreads*	2-5 ( $\frac{1}{4}$ oz)
Low-fat	$\frac{1}{4}$ cup	Graham cracker, $2\frac{1}{2}$ -inch square	3
Regular <sup>†</sup>	$\frac{1}{4}$ cup	Matzoh	$\frac{3}{4}$ oz
Grits, cooked	$\frac{1}{2}$ cup	Melba toast, about 2-inch by 4-inch piece	4 pieces
Kasha	$\frac{1}{2}$ cup	Oyster crackers	20
Millet, cooked	$\frac{1}{3}$ cup	Popcorn (microwave popped)	3 cups
Muesli	$\frac{1}{4}$ cup	With butter <sup>†*</sup>	3 cups
Pasta, cooked	$\frac{1}{3}$ cup	No fat added*	3 cups
Polenta, cooked	$\frac{1}{3}$ cup	Lower fat*	3 cups
Quinoa, cooked	$\frac{1}{3}$ cup	Pretzels	$\frac{3}{4}$ oz
Rice, white or brown, cooked	$\frac{1}{3}$ cup	Rice cakes, 4 inches across	2
Tabbouleh (tabouli), prepared	$\frac{1}{2}$ cup	Snack chips	
Wheat germ, dry	3 Tbsp	Fat-free or baked (tortilla, potato), baked pita chips	15-20 ( $\frac{1}{4}$ oz)
Wild rice, cooked	$\frac{1}{2}$ cup	Regular (tortilla, potato) <sup>†</sup>	9-13 ( $\frac{1}{4}$ oz)
<b>Starchy Vegetables</b>		<b>Beans, Peas, and Lentils</b>	
Cassava	$\frac{1}{3}$ cup	The choices on this list count as 1 starch + 1 lean meat.	
Corn	$\frac{1}{2}$ cup	Baked beans*	$\frac{1}{3}$ cup
On cob, large	$\frac{1}{2}$ cob (5 oz)	Beans, cooked (black, garbanzo, kidney, lima, navy, pinto, white)*	$\frac{1}{2}$ cup
Hominy, canned*	$\frac{3}{4}$ cup	Lentils, cooked (brown, green, yellow)*	$\frac{1}{2}$ cup
Mixed vegetables with corn, peas, or pasta*	1 cup	Peas, cooked (black-eyed, split)*	$\frac{1}{2}$ cup
Parsnips*	$\frac{1}{2}$ cup	Refried beans, canned <sup>†*</sup>	$\frac{1}{2}$ cup
Peas, green*	$\frac{1}{2}$ cup		
Plantain, ripe	$\frac{1}{3}$ cup		
<b>Fruits</b>		<b>Selection Tips</b>	
Fresh, frozen, canned, and dried fruits and fruit juices are on this list.		1. Use a food scale to weigh fresh fruits. Practice builds portion skills.	
In general, 1 fruit choice is:		2. The weight listed includes skin, core, seeds, and rind.	
• $\frac{1}{2}$ cup of canned or fresh fruit or unsweetened fruit juice		3. Read the Nutrition Facts on the food label. If 1 serving has more than 15 g of carbohydrate, you may need to adjust the size of the serving.	
• 1 small fresh fruit (4 oz)		4. Portion sizes for canned fruits are for the fruit and a small amount of juice (1 to 2 tablespoons).	
• 2 tablespoons of dried fruit		5. Food labels for fruits may contain the words <i>no sugar added</i> or <i>unsweetened</i> . This means that no sucrose (table sugar) has been added; it <i>does not</i> mean the food contains no sugar.	
<b>Nutrition Tips</b>		6. Fruit canned in <i>extra light syrup</i> has the same amount of carbohydrate per serving as the <i>no sugar added</i> or the <i>juice pack</i> . All canned fruits on the <b>Fruits</b> list are based on one of these three types of pack. Avoid fruit canned in heavy syrup.	
1. A choice on the <b>Fruits</b> list has 15 grams of carbohydrate, 0 grams of protein, 0 grams of fat, and 60 calories.			
2. Fresh, frozen, and dried fruits are good sources of fiber. Fruit juices contain very little fiber. Choose fruits instead of juices whenever possible.			
3. Citrus fruits, berries, and melons are good sources of vitamin C.

**APPENDIX 34.** Exchange Lists for Meal Planning—cont'd

The weight listed includes skin, core, seeds, and rind.

<b>Food</b>	<b>Serving Size</b>	<b>Food</b>	<b>Serving Size</b>
<b>Fruit</b>			
Apple, unpeeled, small	1 (4 oz)	Mango, small	$\frac{1}{2}$ fruit ( $5\frac{1}{2}$ oz) or $\frac{1}{2}$ cup
Apples, dried	4 rings	Nectarine, small	1 (5 oz)
Applesauce, unsweetened	$\frac{1}{2}$ cup	Orange, small*	1 ( $6\frac{1}{2}$ oz)
Apricots		Papaya	$\frac{1}{2}$ fruit or 1 cup cubed (8 oz)
Canned	$\frac{1}{2}$ cup	Peaches	
Dried	8 halves	Canned	$\frac{1}{2}$ cup
Fresh*	4 whole ( $5\frac{1}{2}$ oz)	Fresh, medium	1 (6 oz)
Banana, extra small	1 (4 oz)	Pears	
Blackberries*	$\frac{3}{4}$ cup	Canned	$\frac{1}{2}$ cup
Blueberries	$\frac{3}{4}$ cup	Fresh, large	$\frac{1}{2}$ (4 oz)
Cantaloupe, small	$\frac{1}{3}$ melon or 1 cup cubed (11 oz)	Pineapple	
Cherries		Canned	$\frac{1}{2}$ cup
Sweet, canned	$\frac{1}{2}$ cup	Fresh	$\frac{3}{4}$ cup
Sweet fresh	12 (3 oz)	Plums	
Dates	3	Canned	$\frac{1}{2}$ cup
Dried fruits (blueberries, cherries, cranberries, mixed fruit, raisins)	2 Tbsp	Dried (prunes)	3
Figs		Small	2 (5 oz)
Dried	1 $\frac{1}{2}$	Raspberries*	1 cup
Fresh*	1 $\frac{1}{2}$ large or 2 medium ( $3\frac{1}{2}$ oz)	Strawberries*	1 $\frac{1}{4}$ cup whole berries
Fruit cocktail	$\frac{1}{2}$ cup	Tangerines, small*	2 (8 oz)
Grapefruit		Watermelon	1 slice or 1 $\frac{1}{4}$ cups cubes ( $13\frac{1}{2}$ oz)
Large	$\frac{1}{2}$ (11 oz)		
Sections, canned	$\frac{3}{4}$ cup		
Grapes, small	17 (3 oz)		
Honeydew melon	1 slice or 1 cup cubed (10 oz)		
Kiwi*	1 ( $3\frac{1}{2}$ oz)		
Mandarin oranges, canned	$\frac{3}{4}$ cup		

\*More than 3 grams of dietary fiber per serving.

**Milk**

Different types of milk and milk products are on this list. However, 2 types of milk products are found in other lists:

- Cheeses are on the **Meat and Meat Substitutes** list (because they are rich in protein).
- Cream and other dairy fats are on the **Fats** list.

Milks and yogurts are grouped in 3 categories (fat-free/low-fat, reduced-fat, or whole) based on the amount of fat they have. The following chart shows you what 1 milk choice contains:

	<b>Carbohydrate (grams)</b>	<b>Protein (grams)</b>	<b>Fat (grams)</b>	<b>Calories</b>
Fat-free (skim), low-fat (1%)	12	8	0-3	100
Reduced-fat (2%)	12	8	5	120
Whole	12	8	8	160

Copyright © 2008 by the American Diabetes Association and the American Dietetic Association. Reprinted with permission.

**Nutrition Tips**

1. Milk and yogurt are good sources of calcium and protein.
2. The higher the fat content of milk and yogurt, the more saturated fat and cholesterol it has.
3. Children over the age of 2 and adults should choose lower-fat varieties such as skim, 1%, or 2% milks or yogurts.

**Selection Tips**

1. 1 cup equals 8 fluid oz or  $\frac{1}{2}$  pint.
2. If you choose 2%, or whole-milk foods, be aware of the extra fat.

## APPENDIX 34. Exchange Lists for Meal Planning—cont'd

Food	Serving Size	Count As
<b>Milk and Yogurts</b>		
Fat-free or low-fat (1%)		
Milk, buttermilk, acidophilus milk, Lactaid	1 cup	1 fat-free milk
Evaporated milk	$\frac{1}{2}$ cup	1 fat-free milk
Yogurt, plain or flavored with an artificial sweetener	$\frac{2}{3}$ cup (6 oz)	1 fat-free milk
Reduced-fat (2%)		
Milk, acidophilus milk, kefir, Lactaid	1 cup	1 reduced-fat milk
Yogurt, plain	$\frac{2}{3}$ cup (6 oz)	1 reduced-fat milk
Whole		
Milk, buttermilk, goat's milk	1 cup	1 whole milk
Evaporated milk	$\frac{1}{2}$ cup	1 whole milk
Yogurt, plain	8 oz	1 whole milk
<b>Dairy-Like Foods</b>		
Chocolate milk		
Fat-free	1 cup	1 fat-free milk + 1 carbohydrate
Whole	1 cup	1 whole milk + 1 carbohydrate
Eggnog, whole milk	$\frac{1}{2}$ cup	1 carbohydrate + 2 fats
Rice drink		
Flavored, low-fat	1 cup	2 carbohydrates
Plain, fat-free	1 cup	1 carbohydrate
Smoothies, flavored, regular	10 oz	1 fat-free milk + 2½ carbohydrates
Soy milk		
Light	1 cup	1 carbohydrate + $\frac{1}{2}$ fat
Regular, plain	1 cup	1 carbohydrate + 1 fat
Yogurt		
And juice blends	1 cup	1 fat-free milk + 1 carbohydrate
Low carbohydrate (less than 6 grams carbohydrate per choice)	$\frac{2}{3}$ cup (6 oz)	$\frac{1}{2}$ fat-free milk
With fruit, low-fat	$\frac{2}{3}$ cup (6 oz)	1 fat-free milk + 1 carbohydrate

### Sweets, Desserts, and Other Carbohydrates

You can substitute food choices from this list for other carbohydrate-containing foods (such as those found on the **Starch**, **Fruit**, or **Milk** lists) in your meal plan, even though these foods have added sugars or fat.

### Common Measurements

#### Dry:

3 tsp = 1 Tbsp  
4 oz =  $\frac{1}{2}$  cup  
8 oz = 1 cup

#### Liquid:

4 Tbsp =  $\frac{1}{4}$  cup  
8 oz =  $\frac{1}{2}$  pint

#### Nutrition Tips

1. A carbohydrate choice has 15 grams of carbohydrate, variable grams of protein, variable grams of fat, and variable calories.

2. The foods on this list do not have as many vitamins, minerals, and fiber as the choices on the **Starch**, **Fruits**, or **Milk** lists. When choosing sweets, desserts, and other carbohydrate foods, you should also eat foods from other food lists to balance out your meals.
3. Many of these foods don't equal a single choice. Some will also count as one or more fat choices.
4. If you are trying to lose weight, choose foods from this list less often.
5. The serving sizes for these foods are small because of their fat content.

#### Selection Tips

1. Read the Nutrition facts on the food label to find the serving size and nutrient information.
2. Many sugar-free, fat-free, or reduced-fat products are made with ingredients that contain carbohydrate. These types of food usually have the same amount of carbohydrate as the regular foods they are replacing. Talk with your RD and find out how to fit these foods into your meal plan.

Food	Serving Size	Count As
<b>Beverages, Soda, and Energy/Sports Drinks</b>		
Cranberry juice cocktail	$\frac{1}{2}$ cup	1 carbohydrate
Energy drink	1 can (8.3 oz)	2 carbohydrates
Fruit drink or lemonade	1 cup (8 oz)	2 carbohydrates
Hot chocolate		
Regular	1 envelope added to 8 oz water	1 carbohydrate + 1 fat
Sugar-free or light	1 envelope added to 8 oz water	1 carbohydrate
Soft drink (soda), regular	1 can (12 oz)	2½ carbohydrates
Sports drink	1 cup (8 oz)	1 carbohydrate

*Continued*

**APPENDIX 34.** Exchange Lists for Meal Planning—cont'd

Food	Serving Size	Count As
<b>Brownies, Cake, Cookies, Gelatin, Pie, and Pudding</b>		
Brownie, small, unfrosted	1¼ -inch square, ⅛ inch high (about 1 oz)	1 carbohydrate + 1 fat
Cake		
Angel food, unfrosted	½ of cake (about 2 oz)	2 carbohydrates
Frosted	2-inch square (about 2 oz)	2 carbohydrates + 1 fat
Unfrosted	2-inch square (about 2 oz)	1 carbohydrate + 1 fat
Cookies		
Chocolate chip	2 cookies (2¼ inches across)	1 carbohydrate + 2 fats
Gingersnap	3 cookies	1 carbohydrate
Sandwich, with creme filling	2 small (about ⅓ oz)	1 carbohydrate + 1 fat
Sugar-free	3 small or 1 large (¾-1 oz)	1 carbohydrate + 1-2 fats
Vanilla wafer	5 cookies	1 carbohydrate + 1 fat
Cupcake, frosted	1 small (about 1¾ oz)	2 carbohydrates + 1-1½ fats
Fruit cobbler	½ cup (3½ oz)	3 carbohydrates + 1 fat
Gelatin, regular	½ cup	1 carbohydrate
Pie		
Commercially prepared fruit, 2 crusts	⅙ of 8-inch pie	3 carbohydrates + 2 fats
Pumpkin or custard	⅛ of 8-inch pie	1½ carbohydrates + 1½ fats
Pudding		
Regular (made with reduced-fat milk)	½ cup	2 carbohydrates
Sugar-free or sugar- and fat-free (made with fat-free milk)	½ cup	1 carbohydrate
<b>Candy, Spreads, Sweets, Sweeteners, Syrups, and Toppings</b>		
Candy bar, chocolate/peanut	2 "fun size" bars (1 oz)	1½ carbohydrates + 1½ fats
Candy, hard	3 pieces	1 carbohydrate
Chocolate "kisses"	5 pieces	1 carbohydrate + 1 fat
Coffee creamer		
Dry, flavored	4 tsp	½ carbohydrate + ½ fat
Liquid, flavored	2 Tbsp	1 carbohydrate
Fruit snacks, chewy (pureed fruit concentrate)	1 roll (¾ oz)	1 carbohydrate
Fruit spreads, 100% fruit	1½ Tbsp	1 carbohydrate
Honey	1 Tbsp	1 carbohydrate
Jam or jelly, regular	1 Tbsp	1 carbohydrate
Sugar	1 Tbsp	1 carbohydrate
Syrup		
Chocolate	2 Tbsp	2 carbohydrates
Light (pancake type)	2 Tbsp	1 carbohydrate
Regular (pancake type)	1 Tbsp	1 carbohydrate
<b>Condiments and Sauces</b>		
Barbeque sauce	3 Tbsp	1 carbohydrate
Cranberry sauce, jellied	¼ cup	1½ carbohydrates
Gravy, mushroom, canned <sup>‡</sup>	½ cup	½ carbohydrate + ½ fat
Salad dressing, fat-free, low fat, cream-based	3 Tbsp	1 carbohydrate
Sweet and sour sauce	3 Tbsp	1 carbohydrate
<b>Doughnuts, Muffins, Pastries, and Sweet Breads</b>		
Banana nut bread	1-inch slice (1 oz)	2 carbohydrates + 1 fat
Doughnut		
Cake, plain	1 medium (1½ oz)	1½ carbohydrates + 2 fats
Glazed	¾ inches across (2 oz)	2 carbohydrates + 2 fats
Muffin (4 oz)	¼ muffin (1 oz)	1 carbohydrate + ½ fat
Sweet roll or Danish	1 (2½ oz)	2½ carbohydrates + 2 fats
<b>Frozen Bars, Frozen Desserts, Frozen Yogurt, and Ice Cream</b>		
Frozen pops	1	½ carbohydrate
Fruit juice bars, frozen, 100% juice	1 bar (3 oz)	1 carbohydrate
Ice cream		
Fat-free	½ cup	1½ carbohydrates
Light	½ cup	1 carbohydrate + 1 fat
No sugar added	½ cup	1 carbohydrate + 1 fat
Regular	½ cup	1 carbohydrate + 2 fats
Sherbet, sorbet	½ cup	2 carbohydrates
Yogurt, frozen		
Fat-free	⅓ cup	1 carbohydrate
Regular	½ cup	1 carbohydrate + 0-1 fat

## APPENDIX 34. Exchange Lists for Meal Planning—cont'd

Food	Serving Size	Count As
<b>Granola Bars, Meal Replacement Bars/Shakes, and Trail Mix</b>		
Granola or snack bar, regular or low-fat	1 bar (1 oz)	1½ carbohydrates
Meal replacement bar	1 bar (1½ oz)	1½ carbohydrates + 0-1 fat
Meal replacement bar	1 bar (2 oz)	2 carbohydrates + 1 fat
Meal replacement shake, reduced calorie	1 can (10-11 oz)	1½ carbohydrates + 0-1 fat
Trail mix		
Candy/nut-based	1 oz	1 carbohydrate + 2 fats
Dried fruit-based	1 oz	1 carbohydrate + 1 fat

<sup>‡</sup>480 mg or more of sodium per serving.

### Nonstarchy Vegetables

Vegetable choices include vegetables in this **Nonstarchy Vegetables** list and the Starchy Vegetables list found within the **Starch** list.

Vegetables with small amounts of carbohydrate and calories are on the **Nonstarchy Vegetables** list. Vegetables contain important nutrients. Try to eat at least 2 to 3 nonstarchy vegetable choices each day (as well as choices from the Starchy Vegetables list). In general, 1 nonstarchy vegetable choice is:

- ½ cup of cooked vegetables or vegetable juice
- 1 cup of raw vegetables

If you eat 3 cups or more of raw vegetables or 1½ cups of cooked vegetables in a meal, count them as 1 carbohydrate choice.

### Nutrition Tips

1. A choice on this list (½ cup cooked or 1 cup raw) equals 5 grams of carbohydrate, 2 grams of protein, 0 grams of fat, and 25 calories.
2. Fresh and frozen vegetables have less added salt than canned vegetables. Drain and rinse canned vegetables to remove some salt.

### Nonstarchy Vegetables

Amaranth or Chinese spinach	Cucumber	Peppers (all varieties)*
Artichoke	Eggplant	Radishes
Artichoke hearts	Gourds (bitter, bottle, luffa, bitter melon)	Rutabaga
Asparagus	Green onions or scallions	Sauerkraut <sup>‡</sup>
Baby corn	Greens (collard, kale, mustard, turnip)	Soybean sprouts
Bamboo shoots	Hearts of palm	Spinach
Beans (green, wax, Italian)	Jicama	Squash (summer, crookneck, zucchini)
Bean sprouts	Kohlrabi	Sugar pea snaps
Beets	Leeks	Swiss chard*
Borscht <sup>‡</sup>	Mixed vegetables (without corn, peas, or pasta)	Tomato
Broccoli	Mung bean sprouts	Tomatoes, canned
Brussels sprouts*	Mushrooms, all kinds, fresh	Tomato sauce <sup>‡</sup>
Cabbage (green, bok choy, Chinese)	Okra	Tomato/vegetable juice <sup>‡</sup>
Carrots*	Onions	Turnips
Cauliflower	Oriental radish or daikon	Water chestnuts
Celery	Pea pods	Yard-long beans
Chayote*		
Coleslaw, packaged, no dressing		

\*More than 3 grams of dietary fiber per serving.

<sup>‡</sup>480 milligrams or more of sodium per serving.

### Meat and Meat Substitutes

Meat and meat substitutes are rich in protein. Foods from this list are divided into 4 groups based on the amount of fat they contain. These groups are lean meat, medium-fat meat, high-fat meat, and plant-based proteins. The following chart shows you what one choice includes:

3. Choose dark green and dark yellow vegetables each day. Spinach, broccoli, romaine, carrots, chilies, squash, and peppers are great choices.
4. Brussels sprouts, broccoli, cauliflower, greens, peppers, spinach, and tomatoes are good sources of vitamin C.
5. Eat vegetables from the cruciferous family several times each week. Cruciferous vegetables include bok choy, broccoli, brussels sprouts, cabbage, cauliflower, collards, kale, kohlrabi, radishes, rutabaga, turnip, and watercress.

### Selection Tips

1. Canned vegetables and juices are also available without added salt.
2. A 1-cup portion of broccoli is a portion about the size of a regular light bulb.
3. Starchy vegetables such as corn, peas, winter squash, and potatoes that have more calories and carbohydrates are on the Starchy Vegetables section in the **Starch** list.
4. The tomato sauce referred to in this list is different from spaghetti/pasta sauce, which is on the Starchy Vegetables list.

	Carbohydrate (grams)	Protein (grams)	Fat (grams)	Calories
Lean meat	—	7	0-3	45
Medium-fat meat	—	7	4-7	75
High-fat meat	—	7	8+	100
Plant-based protein	Varies	7	Varies	Varies

## APPENDIX 34. Exchange Lists for Meal Planning—cont'd

### Nutrition Tips

1. Read labels to find foods low in fat and cholesterol. Try for 3 grams of fat or less per serving.
2. Read labels to find "hidden" carbohydrate. For example, hot dogs actually contain a lot of carbohydrate. Most hot dogs are also high in fat, but are often sold in lower-fat versions.
3. Whenever possible, choose lean meats.
  - a. Select grades of meat that are the leanest.
  - b. Choice grades have a moderate amount of fat.
  - c. Prime cuts of meat have the highest amount of fat.
4. Fish such as herring, mackerel, salmon, sardines, halibut, trout, and tuna are rich in omega-3 fats, which may help reduce risk for heart disease. Choose fish (not commercially fried fish fillets) two or more times each week.

Food	Amount
<b>Lean Meats and Meat Substitutes</b>	
Beef: Select or Choice grades trimmed of fat: ground round, roast (chuck, rib, rump), round, sirloin, steak (cubed, flank, porterhouse, T-bone), tenderloin	1 oz
Beef jerky <sup>†</sup>	1 oz
Cheeses with 3 grams of fat or less per oz	1 oz
Cottage cheese	1/4 cup
Egg substitutes, plain	1/4 cup
Egg whites	2
Fish, fresh or frozen, plain: catfish, cod, flounder, haddock, halibut, orange roughy, salmon, tilapia, trout, tuna	1 oz
Fish, smoked: herring or salmon (lox) <sup>‡</sup>	1 oz
Game: buffalo, ostrich, rabbit, venison	1 oz
Hot dog with 3 grams of fat or less per oz <sup>‡</sup> (8 dogs per 14 oz package) ( <i>Note: Maybe high in carbohydrate</i> )	1
Lamb: chop, leg, or roast	1 oz

<sup>†</sup>480 milligrams or more of sodium per serving.

Food	Amount
<b>Medium-Fat Meat and Meat Substitutes</b>	
Beef: corned beef, ground beef, meatloaf, Prime grades trimmed of fat (prime rib), short ribs, tongue	1 oz
Cheeses with 4-7 grams of fat per oz: feta, mozzarella, pasteurized processed cheese spread, reduced-fat cheeses, string	1 oz
Egg ( <i>Note: High in cholesterol, so limit to 3 per week</i> )	1

<sup>‡</sup>480 milligrams or more of sodium per serving.

The following foods are high in saturated fat, cholesterol, and calories and may raise blood cholesterol levels if eaten on a regular basis. Try to eat 3 or fewer servings from this group per week.

### High-Fat Meat and Meat Substitutes

Food	Amount
Bacon	
Pork <sup>‡</sup>	2 slices (16 slices per lb or 1 oz each, before cooking)
Turkey <sup>‡</sup>	3 slices (1/2 oz each before cooking)
Cheese, regular: American, bleu, brie, cheddar, hard goat, Monterey jack, queso, and Swiss	1 oz
Hot dog: beef, pork, or combination (10 per lb-sized package) <sup>††</sup>	1

<sup>†</sup>Extra fat, or prepared with added fat. (Add an additional fat choice to this food.)

<sup>‡</sup>480 milligrams or more of sodium per serving.

Copyright © 2008 by the American Diabetes Association and the American Dietetic Association. Reprinted with permission.

5. Bake, roast, broil, grill, poach, steam, or boil instead of frying.

### Selection Tips

1. Trim off visible fat or skin.
2. Roast, broil, or grill meat on a rack so that the fat will drain off during cooking.
3. Use a nonstick spray and a nonstick pan to brown or fry foods.
4. Some processed meats, seafood, and soy products contain carbohydrate. Read the food label to see if the amount of carbohydrate in the serving size you plan to eat is close to 13 grams. If so, count it as 1 carbohydrate choice and 1 or more meat choice.
5. Meat or fish that is breaded with cornmeal, flour, or dried bread crumbs contain carbohydrate. Count 3 Tbsp of one of these dry grains as 15 grams of carbohydrate.

Food	Amount
Organ meats: heart, kidney, liver ( <i>Note: Maybe high in cholesterol</i> )	1 oz
Oysters, fresh or frozen	6 medium
Pork, lean	
Canadian bacon <sup>†</sup>	1 oz
Rib or loin chop/roast, ham, tenderloin	1 oz
Poultry, without skin: Cornish hen, chicken, domestic duck or goose (well-drained of fat), turkey	1 oz
Processed sandwich meats with 3 grams of fat or less per oz: chipped beef, deli thin-sliced meats, turkey ham, turkey kielbasa, turkey pastrami	1 oz
Salmon, canned	1 oz
Sardines, canned	2 medium
Sausage with 3 grams of fat or less per oz <sup>‡</sup>	1 oz
Shellfish: clams, crab, imitation shellfish, lobster, scallops, shrimp	1 oz
Tuna, canned in water or oil, drained	1 oz
Veal, loin chop, roast	1 oz

Food	Amount
Fish, any fried product	1 oz
Lamb: ground, rib roast	1 oz
Pork: cutlet, shoulder roast	1 oz
Poultry: chicken with skin; dove, pheasant, wild duck, or goose; fried chicken; ground turkey	1 oz
Ricotta cheese	2 oz or 1/4 cup
Sausage with 4-7 grams of fat per oz <sup>‡</sup>	1 oz
Veal, cutlet (no breading)	1 oz

### High-Fat Meat and Meat Substitutes

Food	Amount
Hot dog: turkey or chicken (10 per lb-sized package) <sup>‡</sup>	1
Pork: ground, sausage, spareribs	1 oz
Processed sandwich meats with 8 grams of fat or more per oz: bologna, pastrami, hard salami	1 oz
Sausage with 8 grams fat or more per oz: bratwurst, chorizo, Italian, knockwurst, Polish, smoked, summer <sup>††</sup>	1 oz

## APPENDIX 34. Exchange Lists for Meal Planning—cont'd

Because carbohydrate content varies among plant-based proteins, you should read the food label.

Food	Amount	Countas
<b>Plant-Based Proteins</b>		
"Bacon" strips, soy-based	3 strips	1 medium-fat meat
Baked beans*	½ cup	1 starch + 1 lean meat
Beans, cooked: black, garbanzo, kidney, lima, navy, pinto, white*	½ cup	1 starch + 1 lean meat
"Beef" or "sausage" crumbles, soy-based*	2 oz	½ carbohydrate + 1 lean meat
"Chicken" nuggets, soy-based	2 nuggets (1½ oz)	½ carbohydrate + 1 medium-fat meat
Edamame*	½ cup	½ carbohydrate + 1 lean meat
Falafel (spiced chickpea and wheat patties)	3 patties (about 2 inches across)	1 carbohydrate + 1 high-fat meat
Hot dog, soy-based	1 (1½ oz)	½ carbohydrate + 1 lean meat
Hummus*	½ cup	1 carbohydrate + 1 high-fat meat
Lentils, brown, green, or yellow*	½ cup	1 carbohydrate + 1 lean meat
Meatless burger, soy-based*	3 oz	½ carbohydrate + 2 lean meats
Meatless burger, vegetable- and starch-based*	1 patty (about 2½ oz)	1 carbohydrate + 2 lean meats
Nut spreads: almond butter, cashew butter, peanut butter, soy nut butter	1 Tbsp	1 high-fat meat
Peas, cooked: black-eyed and split peas*	½ cup	1 starch + 1 lean meat
Refried beans, canned†*	½ cup	1 starch + 1 lean meat
"Sausage" patties, soy-based	1 (1½ oz)	1 medium-fat meat
Soy nuts, unsalted	¾ oz	½ carbohydrate + 1 medium-fat meat
Tempeh	½ cup	1 medium-fat meat
Tofu	4 oz (½ oz)	1 medium-fat meat
Tofu, light	4 oz (½ oz)	1 lean meat

\*More than 3 grams of dietary fiber per serving.

†480 milligrams or more of sodium per serving.

### Fats

Fats are divided into 3 groups, based on the main type of fat they contain:

- **Unsaturated fats** (omega-3, monounsaturated, and polyunsaturated) are primarily vegetable and are liquid at room temperature. These fats have good health benefits.
  - **Omega-3 fats** are a type of polyunsaturated fat and can help lower triglyceride levels and the risk of heart disease.
  - **Monounsaturated fats** also help lower cholesterol levels and may help raise HDL (good) cholesterol levels.
  - **Polyunsaturated fats** can help lower cholesterol levels.
- **Saturated fats** have been linked with heart disease. They can raise LDL (bad) cholesterol levels and should be eaten in small amounts. Saturated fats are solid at room temperature.
- **Trans fats** are made in a process that changes vegetable oils into semi-solid fats. These fats can raise blood cholesterol levels and should be eaten in small amounts. Partially hydrogenated and hydrogenated fats are types of man-made *trans* fats and should be avoided. *Trans* fats are also found naturally occurring in some animal products such as meat, cheese, butter, and dairy products.

### Nutrition Tips

1. A choice on the **Fats** list contains 5 grams of fat and 45 calories.
2. All fats are high in calories. Limit serving sizes for good nutrition and health.
3. Limit the amount of fried foods you eat.
4. Nuts and seeds are good sources of unsaturated fats if eaten in moderation. They have small amounts of fiber, protein, and magnesium.

Food	Serving Size	Food	Serving Size
<b>Unsaturated Fats—Monounsaturated Fats</b>			
Avocado, medium	2 Tbsp (1 oz)	Nuts	
Nut butters ( <i>trans</i> fat-free): almond butter, cashew butter, peanut butter (smooth or crunchy)	1½ tsp	Almonds	6 nuts
		Brazil	2 nuts
		Cashews	6 nuts
		Filberts (hazelnuts)	5 nuts

## APPENDIX 34. Exchange Lists for Meal Planning—cont'd

Food	Serving Size	Food	Serving Size
Macadamia	3 nuts		
Mixed (50% peanuts)	6 nuts	Saturated Fats	
Peanuts	10 nuts	Bacon, cooked, regular or turkey	1 slice
Pecans	4 halves	Butter	
Pistachios	16 nuts	Reduced-fat	1 Tbsp
Oil: canola, olive, peanut	1 tsp	Stick	1 tsp
Olives		Whipped	2 tsp
Black (ripe)	8 large	Butter blends made with oil	
Green, stuffed	10 large	Reduced-fat or light	1 Tbsp
<b>Polyunsaturated Fats</b>		Regular	1½ tsp
Margarine: lower-fat spread (30%–50% vegetable oil, <i>trans</i> fat-free)	1 Tbsp	Chitterlings, boiled	2 Tbsp (½ oz)
Margarine: stick, tub ( <i>trans</i> fat-free), or squeeze ( <i>trans</i> fat-free)	1 tsp	Coconut, sweetened, shredded	2 Tbsp
Mayonnaise		Coconut milk	
Reduced-fat	1 Tbsp	Light	½ cup
Regular	1 tsp	Regular	1½ Tbsp
Mayonnaise-style salad dressing		Cream	
Reduced-fat	1 Tbsp	Half and half	2 Tbsp
Regular	2 tsp	Heavy	1 Tbsp
Nuts		Light	1½ Tbsp
Walnuts, English	4 halves	Whipped	2 Tbsp
Pignolia (pine nuts)	1 Tbsp	Whipped, pressurized	¼ cup
Oil: corn, cottonseed, flaxseed, grape seed, safflower, soybean, sunflower	1 tsp	Cream cheese	
Oil: made from soybean and canola oil—Enova	1 tsp	Reduced-fat	1½ Tbsp (¾ oz)
Plant stanol esters		Regular	1 Tbsp (½ oz)
Light	1 Tbsp	Lard	1 tsp
Regular	2 tsp	Oil: coconut, palm, palm kernel	1 tsp
Salad dressing		Salt pork	¼ oz
Reduced-fat (Note: May be high in carbohydrate) <sup>†</sup>	2 Tbsp	Shortening, solid	1 tsp
Regular <sup>‡</sup>	1 Tbsp	Sour cream	
Seeds		Reduced-fat or light	3 Tbsp
Flaxseed, whole	1 Tbsp	Regular	2 Tbsp
Pumpkin, sunflower	1 Tbsp		
Sesame seeds	1 Tbsp		
Tahini or sesame paste	2 tsp		

<sup>†</sup>480 milligrams or more of sodium per serving.

### Free Foods

A “free” food is any food or drink choice that has less than 20 calories and 5 grams or less of carbohydrate per serving.

### Selection Tips

1. Most foods on this list should be limited to 3 servings (as listed here) per day. Spread out the servings throughout the day.

If you eat all 3 servings at once, it could raise your blood glucose level.

2. Food and drink choices listed here without a serving size can be eaten whenever you like.

Food	Serving Size	Food	Serving Size
<b>Low Carbohydrate Foods</b>			
Cabbage, raw	½ cup	Jam or jelly, light or no sugar added	2 tsp
Candy, hard (regular or sugar-free)	1 piece	Rhubarb, sweetened with sugar substitute	½ cup
Carrots, cauliflower, or green beans, cooked	¼ cup	Salad greens	
Cranberries, sweetened with sugar substitute	½ cup	Sugar substitutes (artificial sweeteners)	
Cucumber, sliced	½ cup	Syrup, sugar-free	2 Tbsp
Gelatin		<b>Modified Fat Foods with Carbohydrate</b>	
Dessert, sugar-free		Cream cheese, fat-free	1 Tbsp (½ oz)
Unflavored		Creamers	
Gum		Nondairy, liquid	1 Tbsp
		Nondairy, powdered	2 tsp

## APPENDIX 34. Exchange Lists for Meal Planning—cont'd

Food	Serving Size	Food	Serving Size
Margarine spread		Honey mustard	1 Tbsp
Fat-free	1 Tbsp	Horseradish	
Reduced-fat	1 tsp	Lemon juice	
Mayonnaise		Miso	1½ tsp
Fat-free	1 Tbsp	Mustard	
Reduced-fat	1 tsp	Parmesan cheese, freshly grated	1 Tbsp
Mayonnaise-style salad dressing		Pickle relish	1 Tbsp
Fat-free	1 Tbsp	Pickles	
Reduced-fat	1 tsp	Dill <sup>†</sup>	1½ medium
Salad dressing		Sweet, bread and butter	2 slices
Fat-free or low-fat	1 Tbsp	Sweet, gherkin	¼ oz
Fat-free, Italian	2 Tbsp	Salsa	¼ cup
Sour cream, fat-free or reduced-fat	1 Tbsp	Soy sauce, light or regular <sup>‡</sup>	1 Tbsp
Whipped topping		Sweet and sour sauce	2 tsp
Light or fat-free	2 Tbsp	Sweet chili sauce	2 tsp
Regular	1 Tbsp	Taco sauce	1 Tbsp
<b>Condiments</b>		Vinegar	
Barbecue sauce	2 tsp	Yogurt, any type	2 Tbsp
Catsup (ketchup)	1 Tbsp		

<sup>†</sup>480 milligrams or more of sodium per serving.

### Free Snacks

These foods in these serving sizes are perfect free-food snacks:

- 5 baby carrots and celery sticks
- ¼ cup blueberries
- ½ oz sliced cheese, fat-free
- 10 goldfish-style crackers
- 2 saltine-type crackers
- 1 frozen cream pop, sugar-free
- ½ oz lean meat
- 1 cup light popcorn
- 1 vanilla wafer

### Drinks/Mixes

Any food on this list—without a serving size listed—can be consumed in any moderate amount:

- Bouillon, broth, consommé<sup>‡</sup>
- Bouillon or broth, low-sodium
- Carbonated or mineral water
- Club soda
- Cocoa powder, unsweetened (1 Tbsp)
- Coffee, unsweetened or with sugar substitute
- Diet soft drinks, sugar-free
- Drink mixes, sugar-free

- Tea, unsweetened or with sugar substitute

- Tonic water, diet
- Water
- Water, flavored, carbohydrate free

### Seasonings

Any food on this list can be consumed in any moderate amount:

- Flavoring extracts (for example, vanilla, almond, peppermint)
- Garlic
- Herbs, fresh or dried
- Nonstick cooking spray
- Pimento
- Spices
- Hot pepper sauce
- Wine, used in cooking
- Worcestershire sauce

### Combination Foods

Many of the foods you eat are mixed together in various combinations, such as casseroles. These “combination” foods do not fit into any one choice list. This is a list of choices for some typical combination foods. This list will help you fit these foods into your meal plan. Ask your RD for nutrient information about other combination foods you would like to eat, including your own recipes.

Food	Serving Size	Count As
<b>Entrees</b>		
Casserole type (tuna noodle, lasagna, spaghetti with meatballs, chili with beans, macaroni and cheese) <sup>‡</sup>		
	1 cup (8 oz)	2 carbohydrates + 2 medium-fat meats
Stews (beef/other meats and vegetables) <sup>‡</sup>	1 cup (8 oz)	1 carbohydrate + 1 medium-fat meat + 0-3 fats
Tuna salad or chicken salad	½ cup (3½ oz)	½ carbohydrate + 2 lean meats + 1 fat
<b>Frozen Meals/Entrees</b>		
Burrito (beef and bean) <sup>**</sup>	1 (5 oz)	3 carbohydrates + 1 lean meat + 2 fats
Dinner-type meal <sup>†</sup>	Generally 14-17 oz	3 carbohydrates + 3 medium-fat meats + 3 fats
Entree or meal with less than 340 calories <sup>‡</sup>	About 8-11 oz	2-3 carbohydrates + 1-2 lean meats

Copyright © 2008 by the American Diabetes Association and the American Dietetic Association. Reprinted with permission.

**APPENDIX 34.** Exchange Lists for Meal Planning—cont'd

<b>Food</b>	<b>Serving Size</b>	<b>Count As</b>
<b>Pizza</b>		
Cheese/vegetarian, thin crust <sup>†</sup>	1/4 of a 12 inch (4½-5 oz)	2 carbohydrates + 2 medium-fat meats
Meat topping, thin crust <sup>†</sup>	1/4 of a 12 inch (5 oz)	2 carbohydrates + 2 medium-fat meats + 1½ fats
Pocket sandwich <sup>†</sup>	1 (4½ oz)	3 carbohydrates + 1 lean meat + 1-2 fats
Pot pie <sup>†</sup>	1 (7 oz)	2½ carbohydrates + 1 medium-fat meat + 3 fats
<b>Salads (Deli-Style)</b>		
Coleslaw	½ cup	1 carbohydrate + 1½ fats
Macaroni/pasta salad	½ cup	2 carbohydrates + 3 fats
Potato salad <sup>‡</sup>	½ cup	1½-2 carbohydrates + 1-2 fats
<b>Soups</b>		
Bean, lentil, or split pea <sup>†</sup>	1 cup	1 carbohydrate + 1 lean meat
Chowder (made with milk) <sup>†</sup>	1 cup (8 oz)	1 carbohydrate + 1 lean meat + 1½ fats
Cream (made with water) <sup>†</sup>	1 cup (8 oz)	1 carbohydrate + 1 fat
Instant <sup>†</sup>	6 oz prepared	1 carbohydrate
With beans or lentils <sup>†</sup>	8 oz prepared	2½ carbohydrates + 1 lean meat
Miso soup <sup>†</sup>	1 cup	½ carbohydrate + 1 fat
Oriental noodle <sup>‡</sup>	1 cup	2 carbohydrates + 2 fats
Rice (congee)	1 cup	1 carbohydrate
Tomato (made with water) <sup>†</sup>	1 cup (8 oz)	1 carbohydrate
Vegetable beef, chicken noodle, or other broth-type <sup>†</sup>	1 cup (8 oz)	1 carbohydrate

\*More than 3 grams of dietary fiber per serving.

<sup>‡</sup>600 milligrams or more of sodium per serving (for combination food main dishes/meals).

**Fast Foods**

The choices in the **Fast Foods** list are not specific fast food meals or items, but are estimates based on popular foods. You can get specific

nutrition information for almost every fast food or restaurant chain. Ask the restaurant or check its website for nutrition information about your favorite fast foods.

<b>Food</b>	<b>Serving Size</b>	<b>Count As</b>
<b>Breakfast Sandwiches</b>		
Egg, cheese, meat, English muffin <sup>‡</sup>	1 sandwich	2 carbohydrates + 2 medium-fat meats
Sausage biscuit sandwich <sup>‡</sup>	1 sandwich	2 carbohydrates + 2 high-fat meats + 3½ fats
<b>Main Dishes/Entrees</b>		
Burrito (beef and beans) <sup>†*</sup>	1 (about 8 oz)	3 carbohydrates + 3 medium-fat meats + 3 fats
Chicken breast, breaded and fried <sup>†</sup>	1 (about 5 oz)	1 carbohydrate + 4 medium-fat meats
Chicken drumstick, breaded and fried	1 (about 2 oz)	2 medium-fat meats
Chicken nuggets <sup>‡</sup>	6 (about 3½ oz)	1 carbohydrate + 2 medium-fat meats + 1 fat
Chicken thigh, breaded and fried <sup>†</sup>	1 (about 4 oz)	½ carbohydrate + 3 medium-fat meats + 1½ fats
Chicken wings, hot <sup>‡</sup>	6 (5 oz)	5 medium-fat meats + 1½ fats
<b>Oriental</b>		
Beef/chicken/shrimp with vegetables in sauce <sup>‡</sup>	1 cup (about 5 oz)	1 carbohydrate + 1 lean meat + 1 fat
Egg roll, meat <sup>‡</sup>	1 (about 3 oz)	1 carbohydrate + 1 lean meat + 1 fat
Fried rice, meatless	½ cup	½ carbohydrates + 1½ fats
Meat and sweet sauce (orange chicken) <sup>‡</sup>	1 cup	3 carbohydrates + 3 medium-fat meats + 2 fats
Noodles and vegetables in sauce (chow mein, lo mein) <sup>†*</sup>	1 cup	2 carbohydrates + 1 fat
<b>Pizza</b>		
Cheese, pepperoni, regular crust <sup>†</sup>	½ of a 14 inch (about 4 oz)	2½ carbohydrates + 1 medium-fat meat + 1½ fats
Cheese/vegetarian, thin crust <sup>†</sup>	¼ of a 12 inch (about 6 oz)	2½ carbohydrates + 2 medium-fat meats + 1½ fats
<b>Sandwiches</b>		
Chicken sandwich, grilled <sup>†</sup>	1	3 carbohydrates + 4 lean meats
Chicken sandwich, crispy <sup>†</sup>	1	3½ carbohydrates + 3 medium-fat meats + 1 fat

Copyright © 2008 by the American Diabetes Association and the American Dietetic Association. Reprinted with permission.

## APPENDIX 34. Exchange Lists for Meal Planning—cont'd

Food	Serving Size	Count As
Fish sandwich with tartar sauce	1	2½ carbohydrates + 2 medium-fat meats + 2 fats
Hamburger		
Large with cheese <sup>†</sup>	1	2½ carbohydrates + 4 medium-fat meats + 1 fat
Regular	1	2 carbohydrates + 1 medium-fat meat + 1 fat
Hot dog with bun <sup>‡</sup>	1	1 carbohydrate + 1 high-fat meat + 1 fat
Submarine sandwich		
Less than 6 grams fat <sup>†</sup>	6-inch sub	3 carbohydrates + 2 lean meats
Regular <sup>†</sup>	6-inch sub	3½ carbohydrates + 2 medium-fat meats + 1 fat
Taco, hard or soft shell (meat and cheese)	1 small	1 carbohydrate + 1 medium-fat meat + 1½ fats
<b>Salads</b>		
Salad, main dish (grilled chicken type, no dressing or croutons) <sup>†*</sup>	Salad	1 carbohydrate + 4 lean meats
Salad, side, no dressing or cheese	Small (about 5 oz)	1 vegetable
<b>Sides/Appetizers</b>		
French fries, restaurant style <sup>†</sup>		
Small	Small	3 carbohydrates + 3 fats
Medium	Medium	4 carbohydrates + 4 fats
Large	Large	5 carbohydrates + 6 fats
Nachos with cheese <sup>†</sup>	Small (about 4½ oz)	2½ carbohydrates + 4 fats
Onion rings <sup>†</sup>	1 serving (about 3 oz)	2½ carbohydrates + 3 fats
<b>Desserts</b>		
Milkshake, any flavor	12 oz	6 carbohydrates + 2 fats
Soft-serve ice cream cone	1 small	2½ carbohydrates + 1 fat

\*More than 3 grams of dietary fiber per serving.

<sup>†</sup>Extra fat, or prepared with extra fat.

<sup>‡</sup>600 milligrams or more of sodium per serving (for fast food main dishes/meals).

### Alcohol

#### Nutrition Tips

1. In general, 1 alcohol choice (½ oz absolute alcohol) has about 100 calories.

#### Selection Tips

1. If you choose to drink alcohol, you should limit it to 1 drink or less per day for women, and 2 drinks or less per day for men.
2. To reduce your risk of low blood glucose (hypoglycemia), especially if you take insulin or a diabetes pill that increases insulin, always drink alcohol with food.

3. While alcohol, by itself, does not directly affect blood glucose, be aware of the carbohydrate (for example, in mixed drinks, beer, and wine) that may raise your blood glucose.

4. Check with your RD if you would like to fit alcohol into your meal plan.

### Alcoholic Beverage

Alcoholic Beverage	Serving Size	Count As
Beer		
Light (4.2%)	12 fl oz	1 alcohol equivalent + ½ carbohydrate
Regular (4.9%)	12 fl oz	1 alcohol equivalent + 1 carbohydrate
Distilled spirits: vodka, rum, gin, whiskey 80 or 86 proof	1½ fl oz	1 alcohol equivalent
Liqueur, coffee (53 proof)	1 fl oz	1 alcohol equivalent + 1 carbohydrate
Sake	1 fl oz	½ alcohol equivalent
Wine		
Dessert (sherry)	3½ fl oz	1 alcohol equivalent + 1 carbohydrate
Dry, red or white (10%)	5 fl oz	1 alcohol equivalent

## APPENDIX 35. National Dysphagia Diets

The following solid food texture levels have been recommended based on the food properties on the food texture scales.

### Level 1: Dysphagia: Pureed

**Description:** This diet consists of pureed, homogenous, and cohesive foods. Food should be “puddinglike.” No coarse textures, raw fruits or vegetables, nuts, and so forth are allowed. Any foods that require bolus formation, controlled manipulation, or mastication are excluded.

**Rationale:** This diet is designed for people who have moderate to severe dysphagia, with poor oral phase abilities and reduced ability to protect their airway. Close or complete supervision and alternate feeding methods may be required.

Liquid Consistency (circle one)

Thin (includes all  
unthickened  
beverages and  
supplements) Nectarlike

Honeylike

Spoon-thick

### Food Textures for NDD Level 1: Dysphagia: Pureed

Food Groups	Recommended	Avoid	If Thin Liquids Are Allowed, Also May Have
Beverages	Any smooth, homogenous beverages without lumps, chunks, or pulp; beverages may need to be thickened to appropriate consistency	Any beverages with lumps, chunks, seeds, pulp, etc.	Milk, juices, coffee, tea, sodas, carbonated beverages, alcoholic beverages, nutritional supplements, ice chips
Breads	Commercially or facility-prepared pureed bread mixes, pre-gelled slurred breads, pancakes, sweet rolls, Danish pastries, French toast, etc., that are gelled through entire thickness of product	All other breads, rolls, crackers, biscuits, pancakes, waffles, French toast, muffins, etc.	
Cereals <i>(Cereals may have just enough milk to moisten)</i>	Smooth, homogenous, cooked cereals such as farina-type cereals Cereals should have a “puddinglike” consistency	All dry cereals and any cooked cereals with lumps, seeds, chunks Oatmeal	Enough milk or cream with cereals to moisten; they should be blended in well
Desserts	Smooth puddings, custards, yogurt, pureed desserts, and soufflés	Ices, gelatin, frozen juice bars, cookies, cakes, pies, pastry, coarse or textured puddings, bread and rice pudding, fruited yogurt <i>These foods are considered thin liquids and should be avoided if thin liquids are restricted:</i> Frozen malts, milk shakes, frozen yogurt, eggnog, nutritional supplements, ice cream, sherbet, regular or sugar-free gelatin, or any foods that become thin liquid at either room (70° F) or body temperature (98° F)	Frozen malts, yogurt, milk shakes, eggnog, nutritional supplements, ice cream, sherbet, plain regular or sugar-free gelatin
Fats	Butter, margarine, strained gravy, sour cream, mayonnaise, cream cheese, whipped topping Smooth sauces such as white sauce, cheese sauce, or hollandaise sauce	All fats with coarse or chunky additives	
Fruits	Pureed fruits or well-mashed fresh bananas Fruit juices without pulp, seeds, or chunks (may need to be thickened to appropriate consistency if thin liquids are restricted)	Whole fruits (fresh, frozen, canned, dried)	Unthickened fruit juices
Meats and meat substitutes	Pureed meats Braunschweiger Soufflés that are smooth and homogenous Softened tofu mixed with moisture Hummus or other pureed legume spread	Whole or ground meats, fish, or poultry Nonpureed lentils or legumes Cheese, cottage cheese Peanut butter, unless pureed into foods correctly Nonpureed, fried, scrambled, or hard-cooked eggs	
Potatoes and starches	Mashed potatoes or sauce; pureed potatoes with gravy, butter, margarine, or sour cream Well-cooked pasta, noodles, bread dressing, or rice that has been pureed in a blender to smooth, homogenous consistency	All other potatoes, rice, noodles Plain mashed potatoes, cooked grains Nonpureed bread dressing	
Soups	Soups that have been pureed in a blender or strained; may need to be thickened to appropriate viscosity	Soups that have chunks, lumps, etc.	Broth and other thin, strained soups

## APPENDIX 35. National Dysphagia Diets—cont'd

Food Groups	Recommended	Avoid	If Thin Liquids Are Allowed, Also May Have
Vegetables	Pureed vegetables without chunks, lumps, pulp, or seeds Tomato paste or sauce without seeds Tomato or vegetables juice (may need to be thickened to appropriate consistency if juice is thinner than prescribed liquid consistency)	All other vegetables that have not been pureed Tomato sauce with seeds, thin tomato juice	Thin tomato or vegetable juices
Miscellaneous	Sugar, artificial sweetener, salt, finely ground pepper, and spices Ketchup, mustard, barbecue sauce, and other smooth sauces Honey, smooth jellies Very soft, smooth candy such as truffles	Coarsely ground pepper and herbs Chunky fruit preserves and seedy jams Seeds, nuts, sticky foods Chewy candies such as caramels or licorice	Smooth chocolate candy with no nuts, sprinkles, etc.

### Level 2: Dysphagia: Mechanically Altered Characteristics

**Description:** This level consists of foods that are moist, soft-textured, and easily formed into a bolus. Meats are ground or are minced no larger than  $\frac{1}{4}$ -inch pieces; they are still moist, with some cohesion. All foods from NDD Level 1 are acceptable at this level.

**Rationale:** This diet is a transition from the pureed textures to more solid textures. Chewing ability is required. The textures on this level are appropriate for individuals with mild to moderate oral or pharyngeal dysphagia. Patients should be assessed for tolerance to mixed textures. It is expected that some mixed textures are tolerated on this diet.

*Liquid Consistency (circle one)*

Thin (includes all unthickened beverages and supplements)	Nectarlike	Honeylike	Spoon-thick
---	------------	-----------	-------------

**Food Textures for NDD Level 2: Dysphagia: Mechanically Altered (includes all foods on NDD Level 1: Dysphagia: Pureed in addition to the foods listed below)**

Food Groups	Recommended	Avoid	If Thin Liquids Are Allowed, Also May Have
Beverages	All beverages with minimum amounts of texture, pulp, etc.; any texture should be suspended in the liquid and should not precipitate out; may need to be thickened, depending on liquid consistency recommended		Milk, juices, coffee, tea, sodas, carbonated beverages, alcoholic beverages If allowed, nutritional supplements Ice chips
Breads	Soft pancakes, well moistened with syrup or sauce Pureed bread mixes, pregelled or slurried breads that are gelled through entire thickness	All others	
Cereals <i>(Cereals may have <math>\frac{1}{4}</math> cup milk or just enough milk to moisten if thin liquids are restricted. The moisture should be well-blended into food.)</i>	Cooked cereals with little texture, including oatmeal Slightly moistened dry cereals with little texture such as corn flakes, Rice Krispies, Wheaties Unprocessed wheat bran stirred into cereals for bulk <i>Note: If thin liquids are restricted, it is important that all of the liquid is absorbed into the cereal</i>	Very coarse cooked cereals that may contain flaxseed or other seeds or nuts Whole grain dry or coarse cereals Cereals with nuts, seeds, dried fruit, or coconut	Milk or cream for cereals
Desserts	Pudding, custard Soft fruit pies with bottom crust only Crisps and cobblers without seeds or nuts and with soft breading or crumb mixture Canned fruit (excluding pineapple) Soft, moist cakes with icing or slurried cakes Pregelled cookies or soft, moist cookies that have been dunked in milk, coffee, or other liquid	Dry, coarse cakes and cookies Anything with nuts, seeds, coconut, pineapple, or dried fruit Breakfast yogurt with nuts Rice or bread pudding <i>These foods are considered thin liquids and should be avoided if thin liquids are restricted:</i> Frozen malts, milk shakes, frozen yogurt, eggnog, nutritional supplements, ice cream, sherbet, regular or sugar-free gelatin, or any foods that become thin liquid at either room ( $70^{\circ}$ F) or body temperature ( $98^{\circ}$ F)	Ice cream, sherbet, malts, nutritional supplements, frozen yogurt, and other ices Plain gelatin or gelatin with canned fruit, excluding pineapple

*Continued*

**APPENDIX 35.** National Dysphagia Diets—cont'd

Food Groups	Recommended	Avoid	If Thin Liquids Are Allowed, Also May Have
Fats	Butter, margarine, cream for cereal (depending on liquid consistency recommendations), gravy, cream sauces, mayonnaise, salad dressings, cream cheese, cream cheese spreads with soft additives, sour cream, sour cream dips with soft additives, whipped toppings	All fats with coarse or chunky additives	Cream for cereal
Fruits	Soft, drained canned or cooked fruits without seeds or skin Fresh soft, ripe banana Fruit juices with small amount of pulp If thin liquids are restricted, fruit juices should be thickened to appropriate viscosity	Fresh or frozen fruits Cooked fruit with skin or seeds Dried fruits Fresh, canned, or cooked pineapple	Thin fruit juices Watermelon without seeds
Meats, meat substitutes, entrees <i>(Meat pieces should not exceed <math>\frac{1}{4}</math>-inch cube and should be tender.)</i>	Moistened ground or cooked meat, poultry, or fish; moist ground or tender meat may be served with gravy or sauce Casseroles without rice Moist macaroni and cheese, well-cooked pasta with meat sauce, tuna-noodle casserole, soft, moist lasagna Moist meatballs, meatloaf, or fish loaf Protein salads such as tuna or egg without large chunks, celery, or onion Cottage cheese, smooth quiche without large chunks Poached, scrambled, or soft-cooked eggs (egg yolks should not be runny but should be moist and mashable with butter, margarine, or other moisture added to them) (cook eggs to 160° F or use pasteurized eggs for safety) Soufflés may have small soft chunks Tofu Well-cooked, slightly mashed, moist legumes such as baked beans All meats or protein substitutes should be served with sauces or moistened to help maintain cohesiveness in the oral cavity	Dry meats, tough meats such as bacon, sausage, hot dogs, bratwurst Dry casseroles or casseroles with rice or large chunks Cheese slices and cubes Peanut butter Hard-cooked or crisp fried eggs Sandwiches Pizza	
Potatoes and starches	Well-cooked, moistened, boiled, baked, or mashed potatoes Well-cooked shredded hash brown potatoes that are not crisp (all potatoes need to be moist and in sauces) Well-cooked noodles in sauce Spaetzle or soft dumplings that have been moistened with butter or gravy	Potato skins and chips Fried or French-fried potatoes Rice	
Soups	Soups with easy-to-chew or easy-to-swallow meats or vegetables; particle sizes in soups should be $<\frac{1}{2}$ inch (soups may need to be thickened to appropriate consistency, if soup is thinner than prescribed liquid consistency)	Soups with large chunks of meat and vegetables Soups with rice, corn, peas	All soups except those noted in Avoid list
Vegetables	All soft, well-cooked vegetables Vegetables should be $<\frac{1}{2}$ inch; should be easily mashed with a fork	Cooked corn and peas Broccoli, cabbage, Brussels sprouts, asparagus, or other fibrous, nontender, or rubbery cooked vegetables	
Miscellaneous	Jams and preserves without seeds, jelly Sauces, salsas, etc., that may have small tender chunks $<\frac{1}{2}$ inch Soft, smooth chocolate bars that are easily chewed	Seeds, nuts, coconut, sticky foods Chewy candies such as caramel and licorice	

## APPENDIX 35. National Dysphagia Diets—cont'd

Food Groups	Recommended	Avoid	If Thin Liquids Are Allowed, Also May Have
<b>Level 3: Dysphagia: Transition to Regular Diet</b>			
<p><i>Description:</i> This level consists of food of nearly regular textures with the exception of very hard, sticky, or crunchy foods. Foods still need to be moist and should be in bite-size pieces at the oral phase of the swallow.</p> <p><i>Rationale:</i> This diet is a transition to a regular diet. Adequate dentition and mastication are required. The textures of this diet are appropriate for individuals with mild oral or pharyngeal phase dysphagia. Patients should be assessed for tolerance of mixed textures. Mixed textures are expected to be tolerated on this diet.</p> <p><i>Liquid Consistency (circle one)</i></p> <p><b>Thin (unthickened)</b></p> <p>Nectarlike</p> <p>Honeylike</p> <p>Spoon-thick</p>			
<b>Food Textures for NDD Level 3: Dysphagia: Advanced</b>			
Food Groups	Recommended	Avoid	If Thin Liquids Are Allowed, Also May Have
Beverages	Any beverages, depending on recommendations for liquid consistency		Milk, juices, coffee, tea, sodas, carbonated beverages, alcoholic beverages, nutritional supplements Ice chips
Breads	Any well-moistened breads, biscuits, muffins, pancakes, waffles, etc.; need to add adequate syrup, jelly, margarine, butter, etc., to moisten well	Dry bread, toast, crackers, etc. Tough, crusty breads such as French bread or baguettes	
Cereals <i>(Cereals may have ¼ cup milk or just enough milk to moisten if thin liquids are restricted.)</i>	All well-moistened cereals	Coarse or dry cereals such as shredded wheat or All Bran	
Desserts	All others except those on <b>Avoid</b> list	Dry cakes, cookies that are chewy or very dry Anything with nuts, seeds, dry fruits, coconut, pineapple <i>These foods are considered thin liquids and should be avoided if thin liquids are restricted:</i> Frozen malts, milk shakes, frozen yogurt, eggnog, nutritional supplements, ice cream, sherbet, regular or sugar-free gelatin or any foods that become thin liquid at either room (70° F) or body temperature (98° F) All fats with coarse, difficult-to-chew, or chunky additives such as cream-cheese spread with nuts or pineapple	Malts, milk shakes, frozen yogurts, ice cream, and other frozen desserts Nutritional supplements, gelatin, and any other desserts of thin liquid consistency when in the mouth
Fats	All other fats except those on <b>Avoid</b> list	Difficult-to-chew fresh fruits such as apples or pears Stringy, high-pulp fruits such as papaya, pineapple, or mango Fresh fruits with difficult-to-chew peels such as grapes Uncooked dried fruits such as prunes and apricots Fruit leather, fruit roll-ups, fruit snacks, dried fruits	Any fruit juices
Fruits	All canned and cooked fruits Soft, peeled fresh fruits such as peaches, nectarines, kiwi, mangos, cantaloupe, honeydew, watermelon (without seeds) Soft berries with small seeds such as strawberries	Tough, dry meats and poultry Dry fish or fish with bones Chunky peanut butter Yogurt with nuts or coconut	
Meats, meat substitutes, entrees	Thin-sliced, tender, or ground meats and poultry Well-moistened fish Eggs prepared any way Yogurt without nuts or coconut Casseroles with small chunks of meat, ground meats, or tender meats		

Continued

## APPENDIX 35. National Dysphagia Diets—cont'd

Food Groups	Recommended	Avoid	If Thin Liquids Are Allowed, Also May Have
Potatoes and starches	All, including rice, wild rice, moist bread dressing, and tender, fried potatoes	Tough, crisp-fried potatoes Potato skins Dry bread dressing Soups with tough meats Corn or clam chowders Soups that have large chunks of meat or vegetables >1 inch	
Soups	All soups except those in the <b>Avoid</b> list Strained corn or clam chowder (may need to be thickened to appropriate consistency if soup is thinner than prescribed liquid consistency)		All thin soups except those in <b>Avoid</b> list Broth and bouillon
Vegetables	All cooked, tender vegetables Shredded lettuce	All raw vegetables except shredded lettuce Cooked corn Nontender or rubbery cooked vegetables Nuts, seeds, or coconut Chewy caramel or taffy-type candies Candies with nuts, seeds, or coconut	
Miscellaneous	All seasonings and sweeteners All sauces Nonchewy candies without nuts, seeds, or coconut Jams, jellies, honey, preserves

## APPENDIX 36. Renal Diet for Dialysis

Your diet depends on your kidney function. Most of the information here relates to people on dialysis. What is right for others is not always right for you. As your kidney function changes, your diet may change as well. This guide will help you do two things: plan nutritious meals you enjoy and keep your body working at its best. Your renal dietitian will work with you to make any changes needed to your usual meal plan, but this appendix contains helpful guidelines.

### 1. Increase Protein

You will need to eat a high-protein diet. Beef, pork, lamb, fish, shellfish, chicken, eggs, and other animal foods provide most of the protein in your diet. Your protein needs are based on your weight. Most people need at least 6 to 8 oz of protein per day. A deck of cards is about the size of a 3-oz serving of protein.

### 2. Limit Potassium

Most foods contain some potassium, but fruits and vegetables are the easiest to control. Limit fruits, vegetables, and juices to 6 servings per day. A serving is usually  $\frac{1}{2}$  cup.

Do not use salt substitute or "lite" salt because they are made with potassium.

### 3. Limit Salt

Limit the salt you eat. Don't add salt during cooking or at the table. Avoid high-salt foods such as frozen meals; canned or dried foods; "fast foods"; and salted meats such as ham, sausage, and luncheon meats. Use salt-free spices or spice mixes such as Mrs. Dash instead of salt to add flavor to your food.

### 4. Limit Phosphorus

Use only 1 serving of milk or dairy food per day. A serving is usually  $\frac{1}{2}$  to 1 cup. Take phosphate binders such as Tums, PhosLo, Renagel, or Fosrenol with your meals as prescribed by your doctor.

### 5. Fluid

A safe amount of fluid to drink is different for everyone. It depends on how much urine you are making. Try not to drink more than 3 cups (24 oz) of fluid each day plus the amount equal to your urine output. If you are limiting your salt intake, you should not feel thirsty.

Fluids include all beverages and foods that are liquid at room temperature such as Jell-O, ice cream, ice, and soup.

### 6. Poor Appetite and Weight Loss

It is common to have a poor appetite if you are new to dialysis. If your appetite has been poor, try eating small frequent meals and extra snacks.

Try adding high-calorie fats such as butter, margarine, and oils; sauces and gravies; and sour cream, cream cheese, or whipped cream for extra calories. Adding rice, pasta, bread, and rolls to meals also adds calories.

Sugar and sweets such as cakes, candies, and pastries are also a good source of calories if you are not following a diabetic diet.

Talk to your nutritionist about trying a nutritional supplement.

### Protein

When on dialysis, you need to eat a high-protein diet. This is because you lose protein during each dialysis treatment. To stay healthy, you need to eat enough protein for your daily needs and also make up for the amount lost during dialysis. Meat, fish, poultry, eggs, and other animal foods provide most of the protein in your diet. Your body uses protein to build and repair muscles, skin, blood, and other tissues.

### Albumin

Albumin is a protein found in blood. Each month a laboratory test measures your albumin. It is a good way to know how healthy you are. Your albumin level should be more than 3.4 mg/dL.

## APPENDIX 36. Renal Diet for Dialysis—cont'd

### Keeping a Healthy Albumin Level

Make sure that you eat enough protein every day. How much protein you need daily depends on how much you weigh.

Find your weight on the chart below to see how many protein servings you need each day.

### Protein Servings for You

If you weigh:	You need:
40 kg	4-5 servings
50 kg	5-6 servings
60 kg	6-7 servings
70 kg	7-8 servings
80 kg	8-9 servings
90 kg	9-10 servings

Your weight: \_\_\_\_\_ kg

You need: \_\_\_\_\_ protein servings each day

### One Serving of Protein Is:

- 1 egg
- 1 oz cooked meat, fish, poultry
- ½ cup cooked or canned fish, seafood
- ½ cup tofu
- 1 cup milk
- 1 oz cheese
- ¼ cup cottage cheese
- ¼ cup pudding or custard
- 2 Tbsp peanut butter
- 1 scoop protein powder
- ½ protein bar

### Common Serving Sizes

Most people eat protein foods in portions larger than 1 serving. Here are some examples:

- Average hamburger patty (3 oz) = 3 protein servings
- Small beefsteak (3 in × 4 in) = 4 protein servings
- Half chicken breast (3 oz) = 3 protein servings
- Chicken drumstick or thigh (2 oz) = 2 protein servings
- Average pork chop (3 oz) = 3 protein servings
- Fish fillet (3 in × 3 in) = 3 protein servings

### Estimating Serving Sizes

Here are some other easy ways to estimate protein serving sizes:

- Your whole thumb is about the size of 1 oz.
- Three stacked dice are about the size of 1 oz.
- A deck of cards is about the size of 3 oz.
- The palm of your hand is about the size of 3 to 4 oz.
- Your clenched fist is about the size of 1 cup.

### Tips for Eating More Protein

Some people on dialysis dislike the taste of protein. Some people find cooking smells unpleasant. Still others are not able to eat enough protein each day.

The following tips will be helpful:

- Use gravy, sauces, seasonings, or spices to improve or hide flavors.
- Prepare meals ahead of time, or stay away from kitchen smells if they spoil your appetite.
- Eat cooked protein foods cold. Try cold fried chicken, a roast beef sandwich, or shrimp salad.
- Add cut-up meats or beans to soups or salads.
- Use more eggs. Try hardboiled eggs, egg salad sandwiches, custards, or quiches. Stir beaten eggs into casseroles and soups.

- Try other protein foods such as angel food cake, peanut butter, or bean salads.
- Eat a protein bar. Your nutritionist can help you choose one.
- Use a protein powder. Your nutritionist can help you choose one and give you ideas for using it.

### Nutritional Supplements

Nutritional supplements provide extra calories and protein. In general, use one can of supplement as a snack each day. Add one extra can for each meal you miss.

Not all nutritional supplements are safe for dialysis patients. Check with your nutritionist before using any supplement. Here are some of the supplements that are used by people on dialysis:

### Malnutrition

If you are not eating enough meat, fish, poultry, eggs, and other high-protein foods, your albumin level will drop below the recommended level.

If your albumin level is low, the cells in your body cannot hold fluid well. This leads to swelling (edema) and low blood pressure during dialysis. Low albumin increases your risk of death. Patients with albumin levels above 4 have the lowest death rate.

It is also important to eat enough calories. Your nutritionist can help you make sure you are getting plenty of protein and calories.

### Exercise

Try to be active in some way each day (e.g., walk, swim, garden, stretch). Using your muscles helps keep them strong. Protein that is stored in your muscles helps support your albumin level.

### Potassium for People on Hemodialysis

- Most foods have some potassium, but fruits and vegetables are the easiest form to control in your diet. The following list groups vegetables and fruits by the amount of potassium in one serving.
- Remember, there are no foods that you cannot eat on your diet. What is important is the amount of foods you eat and how often you eat them. Keep this list handy for shopping or eating out.
- If there are fruits and vegetables you enjoy that are not on the list, ask your nutritionist about them.

### Most People on Hemodialysis May Have

- 1 serving per day from the high-potassium group
- 2 servings per day from the medium-potassium group
- 2 to 3 servings per day from the low-potassium group

This is approximately 2000 to 3000 mg of potassium per day with the other foods you eat. Check the serving size for each food, listed in parentheses next to the item.

### Soaking Vegetables and Beans

Soaking works well for high-potassium foods such as potatoes, parsnips, sweet potatoes, winter squash, and beans. The procedure for soaking follows.

1. Peel vegetables and slice thinly ( $\frac{1}{8}$  inch). Rinse well. Place them in a bowl of warm water, using four times more water than vegetable. For example, soak 1 cup of sliced vegetables in 4 cups of water. Soak at least 1 hour. Drain and rinse again.
2. Vegetables that have been soaked this way can then be fried, mashed, scalloped, put in soups or stews, or served fresh. If you are boiling the food, use four times more water than food and cook as usual.
3. Dried beans should be cooked and then chopped and soaked, using the preceding directions. Canned beans can simply be chopped, rinsed, and soaked.

*Continued*

**APPENDIX 36.** Renal Diet for Dialysis—cont'd

		<b>Low-Potassium Foods 5-150 mg</b>	<b>Medium-Potassium Foods 150-250 mg</b>	<b>High-Potassium Foods 250-500 mg</b>
			<b>Food Category</b>	
Fruits	Applesauce ( $\frac{1}{2}$ cup) Blackberries ( $\frac{1}{2}$ cup) Blueberries (1 cup) Grapefruit ( $\frac{1}{2}$ cup) Pears, canned ( $\frac{1}{2}$ cup) Pineapple ( $\frac{1}{2}$ cup) Plums, canned ( $\frac{1}{2}$ cup) Raspberries ( $\frac{1}{2}$ cup) Rhubarb, cooked ( $\frac{1}{2}$ cup) Strawberries ( $\frac{1}{2}$ cup) Tangerine (1)	Apple (1 medium), cherries (8-10) Fruit cocktail ( $\frac{1}{2}$ cup) Grapes (10-15) Mango ( $\frac{1}{2}$ medium) Melons: cantaloupe, honeydew ( $\frac{1}{2}$ cup), papaya ( $\frac{1}{2}$ cup) Peaches, canned ( $\frac{1}{2}$ cup) Pear, fresh (1 medium) Plums (2) Watermelon (1 cup)	Apricots (3) Avocados ( $\frac{1}{4}$ ) Banana (1 medium) Dates (5) Figs (3) Kiwi (1) Nectarine (1 medium) Orange (1 medium) Peach, fresh (1 medium) Prunes (5) Raisins and dried fruit ( $\frac{1}{4}$ cup) Artichoke (1 medium) Beans: lima, kidney, navy, pinto ( $\frac{1}{2}$ cup) Greens: beet, collard, mustard, spinach, turnip ( $\frac{1}{2}$ cup) Lentils, split peas, chickpeas, black-eyed peas ( $\frac{1}{2}$ cup) Nuts: all kinds ( $\frac{1}{2}$ cup) Parsnips ( $\frac{1}{2}$ cup) Potatoes ( $\frac{1}{2}$ cup or 1 small) Pumpkin ( $\frac{1}{2}$ cup) Spinach ( $\frac{1}{2}$ cup) Tomato (1 medium) Tomato sauce, tomato salsa ( $\frac{1}{4}$ cup) Winter squash ( $\frac{1}{2}$ cup) Yams, sweet potatoes ( $\frac{1}{2}$ cup)	
Vegetables	Asparagus (4 spears) Bean sprouts ( $\frac{1}{2}$ cup) Cabbage ( $\frac{1}{2}$ cup) Cauliflower ( $\frac{1}{2}$ cup) Corn ( $\frac{1}{2}$ cup) Cucumber ( $\frac{1}{2}$ ) Green and wax beans ( $\frac{1}{2}$ cup) Lettuce (1 cup) Okra (3 pods) Onions ( $\frac{1}{2}$ cup) Peas ( $\frac{1}{2}$ cup) Radishes (5) Rutabagas ( $\frac{1}{2}$ cup) Summer squash ( $\frac{1}{2}$ cup) Turnips ( $\frac{1}{2}$ cup) Water chestnuts (4)	Broccoli ( $\frac{1}{2}$ cup) Brussels sprouts (4-6) Beets ( $\frac{1}{2}$ cup) Carrots ( $\frac{1}{2}$ cup) Celery ( $\frac{1}{2}$ cup) Eggplant ( $\frac{1}{2}$ cup) Mixed vegetables ( $\frac{1}{2}$ cup) Mushrooms ( $\frac{1}{2}$ cup) Peanut butter (2 Tbsp) Pepper, green (1) Potato chips (10) Soaked potatoes ( $\frac{1}{2}$ cup)		
Juices	Apple juice ( $\frac{1}{2}$ cup) Cranberry juices (1 cup) Grape juice, frozen (1 cup) Tang, Hi-C and other fruit drinks (1 cup), Kool-Aid (1 cup) Lemonade and limeade (1 cup) Peach or pear nectar ( $\frac{1}{2}$ cup)	Apricot nectar ( $\frac{1}{2}$ cup) Grape juice, canned ( $\frac{1}{2}$ cup) Grapefruit juice ( $\frac{1}{2}$ cup) Pineapple juice ( $\frac{1}{2}$ cup)	Pomegranate juice ( $\frac{1}{2}$ cup) Prune juice ( $\frac{1}{2}$ cup) Tomato juice ( $\frac{1}{2}$ cup) V-8 juice ( $\frac{1}{2}$ cup)	

**Other High-Potassium Foods**

- Milk is high in potassium. Limit milk to 1 cup per day unless you are told to do otherwise.
- Supplements such as Ensure Plus and Enhancer Plus also contain a lot of potassium. Always speak to your nutritionist before using supplements.
- Most salt substitutes and “lite” salt products are made with potassium. Do not use these products. If you are unsure, ask your nutritionist.

**Shaking the Salt Habit**

Salt, or “sodium chloride,” is found in convenience and preserved foods. Foods that do not spoil easily are usually high in sodium. The more sodium you eat, the thirstier you will be. The following list of foods is grouped by sodium levels.

Following a low-sodium diet can be challenging. This list of sodium levels of foods is meant to help you learn what foods and how much of them you can enjoy.

Remember, there are no foods that you cannot eat on your diet. What is important is the amount of foods you eat and how often you eat them. Keep this list handy for shopping or dining.

**Most People on Dialysis May Have**

- 1 serving per day from the high group
- 1 serving per day from the medium group
- As many servings as desired from the low group
- 3 servings per day from the medium group
- As many servings as you want from the low group

This is 2000 to 3000 mg of sodium per day. Check the serving size for each food, listed in parentheses next to the item.

**Rinsing Canned Foods to Lower Sodium (Canned Vegetables, Chunk or Flaked Fish or Shellfish, Poultry or Meats)**

- Empty can into colander or sieve.
- Drain brine and discard.
- Break up chunks into flakes or smaller pieces.
- Rinse under running water for 1 min.
- Drain food until most moisture is gone.

## APPENDIX 36. Renal Diet for Dialysis—cont'd

	<b>Low-Sodium Foods 1-150 mg</b>	<b>Medium-Sodium Foods 150-250 mg</b>	<b>High-Sodium Foods 250-700 mg</b>
		<b>Food Category</b>	
Breads and cereals	Breads, white, whole grain Cakes, cookies, crepes, doughnuts Cereals: cooked, granola, puffed rice, puffed wheat, Shredded Wheat, Sugar Pops, Sugar Smacks, Sugar Crisps Crackers: graham, low salt, melba toast Macaroni, noodles, spaghetti, rice	Biscuits, rolls, muffins: homemade (1) Pancakes (1) “Ready-to-eat” cereals ( $\frac{1}{4}$ cup) Saltine crackers (6) Sweet roll (1)	All Bran ( $\frac{1}{4}$ cup) Instant mixes: noodles, potatoes, rice ( $\frac{1}{2}$ cup) Instant mixes: biscuits, breads, muffins, rolls (1 serving) Waffles (1)
Condiments	Butter, margarine, oil Horseradish, mustard, spices, herbs, sugar, syrup, Tabasco, vinegar, Worcestershire	Bacon (2 slices) Catsup, steak sauce (1 Tbsp) Commercial salad dressing (1 Tbsp) Gravy (2 Tbsp) Low-sodium soy sauce (2 tsp) Mayonnaise (2 Tbsp) Pickle relish (2 Tbsp) Sweet pickles (2 small) Cheeses (1-oz slice) Cottage cheese ( $\frac{1}{2}$ cup) Pudding ( $\frac{3}{4}$ cup)	Salt ( $\frac{1}{4}$ tsp)
Dairy products	Cheeses: cream, Monterey, Mozzarella, Ricotta, low-salt types Cream: half-and-half, sour, whipping Custard, ice cream, sherbet Milk: all kinds, yogurt Nondairy creamer		Buttermilk (1 cup) Processed cheeses and cheese spreads (1 slice or 2 Tbsp)
Main dishes	All unprocessed meats, fish, poultry Eggs Peanut butter Tuna: low-sodium or rinsed		Broth ( $\frac{1}{2}$ cup) Canned fish, meat ( $\frac{1}{4}$ cup) Canned soups ( $\frac{1}{2}$ cup) Hot dog (1) Luncheon meat (1 slice) Canned entrees (e.g., pork and beans, spaghetti, stew) (1 cup) Sausage (1 oz) Canned tomato sauce or puree ( $\frac{1}{4}$ cup) Frozen vegetables with special sauce ( $\frac{1}{2}$ cup) Sauerkraut ( $\frac{1}{4}$ cup) Commercial dips ( $\frac{1}{4}$ cup) Dill pickle chips (3 slices) Olives (5) Salted nuts ( $\frac{1}{2}$ cup)
Fruits and vegetables	All fresh or frozen vegetables All fruits and juices Canned tomatoes, tomato paste Canned vegetables: low-sodium or rinsed	Vegetables ( $\frac{1}{2}$ cup) Juices: tomato, vegetable ( $\frac{1}{2}$ cup)	
Beverages and snacks	Beer, wine, coffee, tea Candy: all kinds Fruit drinks, Popsicles, soda pop, Kool-Aid, Tang Low-salt products: without potassium substitutes Unsalted nuts, unsalted popcorn	Potato and corn chips (1 cup) Snack crackers (5-10)	

### Phosphorus

#### Low-Phosphorus Diet

When phosphorus is high for too long, bones become brittle and weak.

You may have joint and bone pain. Extra phosphorus may go into your soft tissue, causing hard or soft lumps. Also, you may have severe itching.

The good news is that with diet, binders, and good dialysis, you can keep your phosphorus level under control.

Phosphorus is a mineral found in most foods. Dialysis does not remove it easily. Your phosphorus level depends on the foods you eat and your medications. Keeping your phosphorus at a safe level will help keep your bones healthy.

Each month your phosphorus level will be measured. High phosphorus is a common problem for people on dialysis. A good phosphorus level in your blood is between 3 and 6 g/dL.

#### High-Phosphorus Foods

Phosphorus is found in most foods you eat, especially protein foods.

The foods that are highest in phosphorus are milk and things made from milk (dairy foods).

By limiting these foods you can cut down on the phosphorus you are eating. Most people on dialysis can have one serving daily from this list of dairy foods. The serving size is also noted.

You can also eat part of a serving of different foods to add up to 1 serving.

- Milk (1 cup)
- Cheese (2 oz)
- Cottage cheese ( $\frac{1}{2}$  cup)
- Yogurt (1 cup)
- Ice cream ( $1\frac{1}{2}$  cup)
- Frozen yogurt ( $1\frac{1}{2}$  cup)
- Milkshake (1 cup)
- Hot chocolate (1 cup)
- Pudding or custard (1 cup)

#### Other High-Phosphorus Foods

When your phosphorus level is high, you may need to limit these foods to once a week.

Bran cereals (1 oz)

## APPENDIX 36. Renal Diet for Dialysis—cont'd

Dried beans or peas ( $\frac{1}{2}$  cup cooked)

Chili ( $\frac{1}{2}$  cup)

Nuts ( $\frac{1}{2}$  cup)

Frozen waffles (1)

### Phosphorus and Potassium

High-phosphorus foods are often high in potassium as well. This is another reason to limit dairy foods and other high-phosphorus foods.

### Phosphate Binders

Phosphate binders are pills you take when you eat. Binders help keep phosphorus in your food from going into your blood.

Your doctor will decide which binder is best for you and how many you should take each time you eat.

It is important to take all your binders planned for each day.

You can take your binders just before you start a meal, during the meal, or right after eating.

If you forget to take them or skip a meal, it may be difficult to get your full binder dose. Ask your doctor what to do if this happens.

It may take some hard work to remember to take binders each time you eat. Try these ideas:

- Each morning take out the number of binders you need that day. Put them in a small container to carry with you. It should be empty at the end of the day.
- Carry a spare container of binders for when you travel or eat out.
- Take your binders with high-protein snacks such as sandwiches or dairy foods.
- Binders may cause constipation. Talk with your nutritionist about ideas to help with bowel movements.
- There are many types of binders. If you don't like the kind you are taking, talk with your doctor, pharmacist, or nutritionist about other kinds.

### Lower-Phosphorus Ideas

Following are some lower-phosphorus choices you can make in the place of milk and other creamy dairy products. Check those you will try.

- Use nondairy creamer such as Mocha Mix or Coffee Rich on cereal, for creamy sauces or soups, and in shakes.
- Try rice milk or soymilk. They are lower in potassium too.
- Try soy cheese or soy yogurt. They are available in a variety of flavors.
- Use cream cheese in the place of regular cheese or cottage cheese.
- Use sour cream or imitation sour cream on fruits or to replace yogurt in dips.
- Try a nondairy frozen ice cream made from soy, rice, or nondairy creamer such as Mocha Mix.
- Enjoy sorbet or sherbet instead of ice cream.

### High Phosphorus Levels

Following are some reasons for a high phosphorus level. Check the ones that you think may apply to you:

- Eating too many high-phosphorus foods
- Forgetting to take your binders
- Not taking all the phosphate binders ordered for you
- Not taking your phosphate binders at the right times

Even if you follow your diet and take your binders, your phosphorus level may be high. When calcium and phosphorus are out of balance, your parathyroid gland becomes overactive. High levels of parathyroid hormone damage your bones. Your doctor can test for this problem and recommend treatment.

Appendix created by Katy G. Wilkens, MS, RD.

**NOTE:** Some foods are very high in sodium and should be used only once a week. These include Chinese, Oriental foods; corned beef, ham, pastrami; fast foods (e.g., commercial hamburgers, pizza, tacos); pickles; soy sauce; and TV dinners and frozen entrees.

## APPENDIX 37. Sodium-Restricted Diets

Sodium restriction is used in the management of essential hypertension and for cardiovascular disease, severe cardiac failure, impaired liver function, renal disease, and chronic renal failure. The goal of the sodium-restricted meal plan is to manage hypertension in sodium-sensitive persons and promote the loss of excess fluids in edema and ascites. Sodium is restricted to various degrees to meet the requirement.

### Adequacy

Depending on individual food choices, sodium-restricted meal plans are adequate in all nutrients based on the Dietary Reference Intakes. When sodium is restricted to 1000 mg or less, a calcium supplement may be needed.

### Special Considerations

A large volume of research has assessed the relationship of dietary sodium intake to prevention and treatment of high blood pressure. One result of this research is that sodium in combination with chloride (table salt) may aggravate hypertension in some people who are sensitive to salt. Numerous health agencies agree that sodium intake should be limited to 2.4 g (2400 mg) or less per day for healthy people. 1 tsp salt contains 2300 mg sodium.

A therapeutic sodium-restricted meal plan should be prescribed in terms of milligrams of sodium desired on a daily basis. The following are the commonly used levels of sodium restrictions:

**No Added Salt (NAS):** This is the least restrictive of the sodium-restricted diets. Table salt should not be used, and salt should be limited in cooking. When high-sodium foods such as smoked, cured, or dried meats and cheeses; condiments and seasonings, salted snacks, and canned and dried soups and bouillon are also limited, the NAS diet provides approximately 4000 mg of sodium daily.

**3000 mg sodium (7.5 g NaCl or 130 mEq Na):** This diet *restricts* foods and beverages that have been highly processed with sodium such as fast foods; salad dressings; soy sauce; salty snack foods; smoked, salted, and kosher meats; regular canned foods; pickled vegetables; luncheon meats; and commercially softened water. Up to  $\frac{1}{4}$  tsp salt per day may be used in cooking or at the table.

**2000 mg sodium (5 g NaCl or 87 mEq Na):** This diet *eliminates* processed and prepared foods and beverages that are high in sodium. Salt should not be used in cooking or at the table. Milk and milk products are limited to 16 oz daily. Only salt-free commercially prepared foods should be used.

**1000 mg sodium (2.5 g NaCl or 45 mEq Na):** Processed and prepared foods and beverages that are high in sodium are eliminated. Regular canned foods, many frozen foods, deli foods, fast foods, cheeses, margarines, and regular salad dressings are also eliminated (low-sodium or sodium-free versions should be

## APPENDIX 37. Sodium-Restricted Diets—cont'd

substituted). Regular breads are limited to two servings/day. Milk and milk products are limited to 16 oz/day. Salt should not be used in cooking or at the table. Note: Most medical professionals no longer recommend eating patterns with less than 1000 mg sodium. In addition to being unpalatable, they are very restrictive and could result in nutritional deficiencies if followed for an extended period.

### Guidelines for Sodium Restriction

- Obtain and evaluate a diet history before prescribing or instructing on a sodium restriction.
- Recommend salt substitutes containing potassium chloride only if approved by a physician. Salt-free seasoning products are readily available in most grocery stores and should be suggested instead.
- Instruct patients on reading the Nutrition Facts food label for sodium content of foods.
- Recommend potassium replacement if diuretics are used. If potassium intake from foods is not sufficient, potassium supplements may be necessary.
- Provide information on choosing low-sodium foods at restaurants.
- Recommend baked products, using sodium-free baking powder, potassium bicarbonate (instead of sodium bicarbonate or baking soda), and salt-free shortening in place of those containing sodium.

- Avoid obviously salted foods such as bouillon, soup and gravy bases, canned soups and stews; bread and rolls with salt toppings, salted crackers; salted nuts or popcorn, potato chips, pretzels, and other salted snack foods.
- Avoid smoked or cured meats, such as bacon, bologna, cold cuts, other processed meats, chipped or corned beef, frankfurters, ham, koshered or kosher style meats, and canned meat poultry.
- Avoid salted and smoked fish such as cod, herring, and sardines.
- Avoid sauerkraut, olives, pickles, relishes, and other vegetables prepared in brine, tomato, and vegetable cocktail juices.
- Avoid seasonings such as celery salt, garlic, Worcestershire sauce, and soy sauce.
- Serve cheeses (e.g., Swiss, American, and other processed cheeses) in limited amounts (approximately two times a week).
- Include sodium-containing medications, seltzer waters, toothpaste, and chewing tobacco in total sodium allotment if the restriction is below 2000 mg.
- Monitor the sodium content of various medications, including over-the-counter brands.

### Sodium Content of Selected Over-the-Counter Medications

Medication	Trade Name	Sodium Content	
		Milligrams per Dose	Milligrams per 100 mL
Analgesic	Aspirin (various others)	49	—
Antacid analgesic	Bromo-Seltzer	717	—
Antacid laxative	Alka-Seltzer (blue box)	521	—
Antacids	Sal Hepatica	1000	—
	Rolaids	53	—
	Soda Mint	89	—
	Alka-Seltzer (gold box)	276	—
	Brioschi	710	—
Laxatives	Metamucil Instant Mix	250	—
	Fleet's Enema	250-300	—
Sleep aids	Miles Nervine Effervescent	544	—
Antacid suspensions	Milk of Magnesia	—	10
	Amphojel	—	14
	Basaljel	—	36
	Maalox	—	50
	Riopan	—	14
	Mylanta I	—	76
	Mylanta II	—	160
	Digel	—	170
	Titralac	—	220

**Seasoning without salt:** Flavorings or seasonings will make food more appetizing. For example:

- Lemon or vinegar is excellent with fish or meat and with many vegetables such as broccoli, asparagus, green beans, or salads.
- Meat may be seasoned with onion, garlic, green pepper, nutmeg, ginger, dry mustard, sage and marjoram. It may be cooked with fresh mushrooms or unsalted tomato juice.
- Cranberry sauce, applesauce, or jellies make appetizing accompaniments to meats and poultry.

- Vegetables may be flavored by the addition of onion, mint, ginger, mace, dill seed, parsley, green pepper, or fresh mushrooms.
- Unsalted cottage cheese may be flavored with minced onion, chopped chives, raw green pepper, grated carrots, chopped parsley, or crushed pineapple.
- A number of salt-free seasonings for use in cooking are available in the spice section of most supermarkets.

*Continued*

## APPENDIX 37. Sodium-Restricted Diets—cont'd

### 3000-mg Sodium Diet

Food Category	Recommended	Not Recommended
Beverages	Milk, buttermilk (limit to 1 cup daily); eggnog; all fruit juices; low sodium, salt-free vegetable juices; regular vegetable or tomato juices (limit to $\frac{1}{2}$ cup daily); coffee, tea, low-sodium carbonated beverages	Regular vegetable or tomato juices used in excessive amounts
Breads and cereals	Enriched white, wheat, rye, and pumpernickel bread, hard rolls, and dinner rolls; biscuits, muffins, cornbread, pancakes, and waffles; most dry and hot cereals; unsalted crackers and breadsticks	Breads, rolls, and crackers with salted tops; instant hot cereals
Desserts and sweets	All	None
Fats	Butter or margarine; vegetable oils; low-sodium salad dressing, other salad dressings in limited amounts; light, sour, and heavy cream	Salad dressings containing bacon fat, bacon bits, and salt pork; snack dips made with instant soup mixes or processed cheese
Fruits	All	None
Meats and meat substitutes	Any fresh or frozen beef, lamb, pork, poultry, fish and most shellfish; canned tuna or salmon, rinsed; eggs and egg substitutes; regular cheese, ricotta, and cream cheese (2 oz daily); low-sodium cheese as desired; cottage cheese, drained; regular yogurt; regular peanut butter (3 times weekly); dried peas and beans; frozen dinners (<600 mg sodium)	Any smoked, cured, salted, kosher, commercially prepared meat, fish, or poultry, including bacon, chipped beef, cold cuts, ham, hot dogs, sausage, sardines, anchovies, marinated herring, and pickled meats; frozen breaded meats; pickled eggs; processed cheese, cheese spreads and sauces; salted nuts
Potatoes and potato substitutes	White or sweet potatoes; winter squash; enriched rice, barley, noodles, spaghetti, macaroni, and other pastas; homemade bread stuffing	Commercially prepared potato, rice, or pasta mixes; commercial bread stuffing
Soups	Commercially prepared and dehydrated soups, broths, and bouillons (once per week); homemade broth, soups without added salt and made with allowed vegetables; reduced-sodium commercially prepared soups and broths	Commercially prepared or dehydrated regular soups (more than once per week)
Vegetables	All fresh and frozen vegetables, commercially prepared, drained vegetables	Sauerkraut, pickled vegetables, and others prepared in brine; vegetables seasoned with ham, bacon, or salt pork
Miscellaneous	Limit added salt to $\frac{1}{4}$ tsp/day used at the table or in cooking; salt substitute with physician's approval; pepper, herbs, spices; vinegar, lemon, or lime juice; hot pepper sauce; low-sodium soy sauce (1 tsp); unsalted tortilla chips, pretzels, potato chips, popcorn; salsa (2 Tbsp), catsup and mustard (1 Tbsp), low-sodium baking powder	Any seasoning made with salt, including garlic salt, celery salt, onion salt, and seasoned salt; sea salt, rock salt, kosher salt; meat tenderizers; monosodium glutamate; regular soy sauce, teriyaki sauce, most flavored vinegars; regular snack chips, olives

### Sample Menu for 3000-mg Sodium Diet

Breakfast	Lunch	Dinner
$\frac{1}{2}$ cup calcium-fortified orange juice	3-oz boneless, skinless chicken breast	1 cup spaghetti with meat sauce
$\frac{3}{4}$ cup Raisin Bran	$\frac{1}{2}$ cup white rice	1 cup tossed salad with assorted vegetables
2 slices whole wheat toast	$\frac{1}{2}$ cup broccoli	1 Tbsp low-fat Italian dressing
2 tsp margarine	$\frac{1}{2}$ cup coleslaw	1 slice Italian bread
1 Tbsp jelly	1 whole wheat roll	$\frac{1}{2}$ cup apple crisp
1 cup skim milk	1 tsp margarine	2 tsp margarine
1 cup coffee	1 cup iced tea	1 cup skim milk
2 tsp sugar	$\frac{1}{2}$ cup chocolate pudding	1 cup coffee
	$\frac{1}{2}$ Tbsp whipped topping	$\frac{1}{4}$ tsp pepper
	$\frac{1}{4}$ tsp pepper	2 tsp sugar
	2 tsp sugar	

### Nutritional Analysis

## APPENDIX 37. Sodium-Restricted Diets—cont'd

### 2000-mg Sodium Diet

Food Category	Recommended	Not Recommended
Beverages	Milk (limit to 2 cup daily), buttermilk (limit to 1 cup daily), eggnog, all fruit juices, low-sodium, salt-free vegetable juices, coffee, tea, low-sodium carbonated beverages	Malted milk, milkshakes, chocolate milk, regular vegetable or tomato juices, commercially softened water used for drinking or cooking
Breads and cereals	Enriched, white, wheat, rye, and pumpernickel bread, hard rolls, and dinner rolls; muffins, cornbread, waffles; most dry cereals, cooked cereal without added salt; unsalted crackers and breadsticks; low-sodium or homemade bread crumbs	Breads, rolls, and crackers with salted tops; quick breads; instant hot cereals; commercial bread stuffing; self-rising flour and biscuit mixes; regular bread crumbs or cracker crumbs; pancakes
Desserts and sweets	All; desserts and sweets made with milk should be within allowance	Instant pudding mixes and cake mixes
Fats	Butter or margarine; vegetable oils; unsalted salad dressings; light, sour, and heavy cream; regular salad dressing limited to 1 Tbsp	Regular salad dressings containing bacon fat, bacon bits, and salt pork; snack dips made with instant soup mixes or processed cheese
Fruits	Most fresh, frozen, and canned fruits	Fruits processed with salt or sodium-containing compounds (i.e., some dried fruits)
Meats and meat substitutes	Any fresh or frozen beef, lamb, pork, poultry, fish; some shellfish; canned tuna or salmon, rinsed; eggs and egg substitutes; low-sodium cheese, including low-sodium ricotta and cream cheese; low-sodium cottage cheese; regular yogurt; low-sodium peanut butter; dried peas and beans; frozen dinners (<500 mg sodium)	Any smoked, cured, salted, kosher, commercially prepared meat, fish, or poultry, including bacon, chipped beef, cold cuts, ham, hot dogs, sausage, sardines, anchovies, marinated herring, and pickled meats; crab, lobster, frozen, breaded meats, pickled eggs, regular hard and processed cheese; cheese spreads and sauces; salted nuts
Potatoes and potato substitutes	White or sweet potatoes; winter squash; enriched rice, barley, noodles, spaghetti, macaroni, and other pastas cooked without salt; homemade bread stuffing	Commercially prepared potato, rice, or pasta mixes; commercial bread stuffing
Soups	Low-sodium commercially prepared and dehydrated soups, broth, and bouillon; homemade broth soups made without added salt and with allowed vegetables; cream soups within milk allowance	Regular commercially prepared or dehydrated soups, broth, or bouillon
Vegetables	Fresh, frozen vegetables and low-sodium commercially prepared vegetables	Regular commercially prepared vegetables, sauerkraut, pickled vegetables, and others prepared in brine; frozen vegetables in sauces; vegetables seasoned with ham, bacon, or salt pork
Miscellaneous	Salt substitute with physician's approval; pepper, herbs, spices; vinegar, lemon or lime juice; low-sodium soy sauce (1 tsp); hot pepper sauce; low-sodium condiments (catsup, chili sauce, mustard); fresh ground horseradish; unsalted tortilla chips, pretzels, potato chips, popcorn, salsa (2 Tbsp)	Any seasoning made with salt, including garlic salt, celery salt, onion salt, and seasoned salt; sea salt, rock salt, kosher salt; meat tenderizers, monosodium glutamate; regular soy sauce, barbecue sauce, teriyaki sauce, steak sauce, Worcestershire sauce, most flavored vinegars; canned gravy and mixes; regular condiments; salted snack foods, olives

### Sample Menu for 2000-mg Sodium Diet

Breakfast	Lunch	Dinner
$\frac{1}{2}$ cup calcium-fortified orange juice $\frac{3}{4}$ cup raisin bran 2 slices whole-wheat toast 2 tsp margarine 1 Tbsp jelly 1 cup skim milk 1 cup coffee 2 tsp sugar	3-oz boneless, skinless chicken breast $\frac{1}{2}$ cup white rice $\frac{1}{2}$ cup broccoli $\frac{1}{2}$ cup coleslaw 1 whole-wheat roll 1 tsp margarine $\frac{1}{2}$ cup homemade pudding $\frac{1}{2}$ Tbsp whipped cream 1 cup iced tea $\frac{1}{4}$ tsp pepper 2 tsp sugar	1 cup spaghetti with low-sodium tomato or meat sauce 1 cup tossed salad with assorted vegetables 1 slice Italian bread 1 tsp margarine $\frac{1}{2}$ cup apple crisp 1 cup coffee $\frac{1}{4}$ tsp pepper 2 tsp sugar

## APPENDIX 38. Nutritional Facts on Alcoholic Beverages

Alcohol may have beneficial effects when consumed in moderation. The lowest all-cause mortality occurs at an intake of one to two drinks per day. The lowest coronary heart disease mortality also occurs at an intake of one to two drinks per day. Morbidity and mortality are highest among those drinking large amounts of alcohol. Guidelines:

- Alcoholic beverages should not be consumed by some individuals, including those who cannot restrict their alcohol intake, women of childbearing age who may become pregnant, pregnant and lactating women, children and adolescents, individuals taking medications that can interact with alcohol, and those with specific medical conditions.
- Those who choose to drink alcoholic beverages should do so sensibly and in moderation—defined as the consumption of up to

one drink per day for women and up to two drinks per day for men.

- Alcoholic beverages should be avoided by individuals engaging in activities that require attention, skill, or coordination, such as driving or operating machinery.

### Calories in Selected Alcoholic Beverages\*

This table is a guide to estimate the caloric intake from various alcoholic beverages. A sample serving volume and the calories in that drink are shown for beer, wine, and distilled spirits. Higher alcohol content (higher percent alcohol or higher proof) and mixing alcohol with other beverages such as sweetened soft drinks, tonic water, fruit juice, or cream increase the amount of calories in the beverage. Alcoholic beverages supply calories but provide few essential nutrients.

Beverage	Serving (oz)	Alcohol (g)	Carbohydrate (g)	Calories	Exchanges for Calorie or Diabetes Control
Beer					
Regular	12	13	13	150	1 starch, 2 fat
Light	12	11	5	100	2 fat
Near beer	12	1.5	12	60	1 starch
Distilled spirits					
80-Proof (gin, rum, vodka, whiskey, scotch)	1.5	14	Trace	100	2 fat
Dry brandy, cognac	1	11	Trace	75	1.5 fat
Table wines					
Dry white	4	11	Trace	80	2 fat
Red or rose	4	12	2	85	2 fat
Sweet wine	4	12	5	105	½ starch, 2 fat
Light wine	4	6	1	50	1 fat
Wine cooler	12	13	30	215	2 fruit, 2 fat
Dealcoholized wines	4	Trace	6-7	25-35	0.5 fruit
Sparkling wines					
Champagne	4	12	4	100	2 fat
Sweet kosher wine	4	12	12	132	1 starch, 2 fat
Appetizer and dessert wines					
Sherry	2	9	2	74	1.5 fat
Sweet sherry, port, muscatel	2	9	7	90	0.5 starch, 1.5 fat
Cordials, liqueurs	1	13	18	160	1 starch, 2 fat
Vermouth

Manhattan	2	17	2	178	2.5 fat
Martini	2.5	22	Trace	156	3.5 fat
Old-fashioned	4	26	Trace	180	4 fat
Tom Collins	7.5	16	3	120	2.5 fat
Mixes					
Mineral water	Any	0	0	0	Free
Sugar-free tonic	Any	0	0	0	Free
Club soda	Any	0	0	0	Free
Diet soda	Any	0	0	0	Free
Tomato juice	4	0	5	25	1 vegetable
Bloody Mary mix	4	0	5	25	1 vegetable
Orange juice	4	0	15	60	1 fruit
Grapefruit juice	4	0	15	60	1 fruit
Pineapple juice	4	0	15	60	1 fruit

From Franz MJ: Alcohol and diabetes: its metabolism and guidelines for its occasional use. Part II, Diabetes Spectrum 3(4):210-216, 1990.

\*The caloric contribution from alcohol of an alcoholic beverage can be estimated by multiplying the number of ounces by the proof and then again by the factor 0.8. For beers and wines, kilocalories from alcohol can be estimated by multiplying ounces by percentage of alcohol (by volume) and then by the factor 1.6.

## APPENDIX 39. Nutritional Facts on Caffeine-Containing Products

Caffeine is similar in structure to adenosine, a chemical found in the brain that slows down its activity. Because the two compete, the more caffeine that is consumed, the less adenosine that is available up to a point. Caffeine temporarily heightens concentration and wards off fatigue. Within 30 to 60 minutes of drinking a cup of coffee, caffeine reaches peak concentrations in the bloodstream and takes 4 to 6 hours for its effects to wear off. The average American adult consumes about

200 mg of caffeine a day, and many may consume twice that level. It is generally safe to consume no more than the equivalent amount of caffeine in 1 to 2 cups of coffee daily during pregnancy or lactation. Individuals with heart disease and hypertension may benefit from a reduction in caffeine consumption. To reduce caffeine and its stimulant effects, monitor intake from foods and beverages listed below.

### Selected Food and Beverage Sources of Caffeine

Caffeine-Containing Products	Serving (mg)
<b>Coffee</b>	
Starbucks coffee (in store), 16 oz.	330
Starbucks coffee (at home), 16 oz.	260
Brewed, drip method, 6 oz	103
Brewed, percolator method, 6 oz	75
Instant, 1 rounded tsp	57
Flavored, regular and sugar-free, 6 oz	26-75
Espresso, 1 oz	40
Café Latte, short (8 oz) or tall (12 oz) (Starbucks)	35
Decaffeinated, 6 oz	2
<b>Tea</b>	
Black or green tea, 16 oz	60-100
3-minute brew, 12-oz	72
Lipton, Arizona, or Snapple tea, 16 oz	30-60
Instant, 1 rounded tsp in 8 oz of water	25-35
Tea, green brewed, 8 oz	30
Tea, bottles (12 oz) or from instant mix, 8 oz	14
Decaffeinated, 5- minute brew, 6-oz cup	1
<b>Carbonated Beverages</b>	
7-Eleven Big Gulp cola, 64 oz	190
Mountain Dew MDX or Vault, 12 oz	120
Diet Pepsi Max, 20 oz	70
Mountain Dew, 12 oz, regular or diet	54
Mellow Yellow, 12 oz, regular or diet	52
Regular or diet cola, cherry colas, Dr. Pepper, Mr. Pibb, 12 oz	35-50
Decaffeinated drinks, 12 oz	Trace
<b>Cocoa and Chocolate</b>	
Chocolate, baking, unsweetened, 1 oz	58
Chocolate, sweet, semisweet, dark, milk, 1 oz	8-20
Milk chocolate bar , 1.5 oz	10
Chocolate milk, 8 oz	8
Cocoa beverage, 6-oz cup	4
Chocolate-flavored syrup, 1 oz	5
Chocolate pudding, $\frac{1}{2}$ cup	4-8
<b>Miscellaneous</b>	
Powershot (8 oz)	800
Rock Star, 16 oz	240
NoDoz, Maximum Strength (1), or Vivarin (1)	200
Pit Bull Energy Bar, 2 oz	165
Excedrin (2)	130
NoDoz, Regular Strength (1)	100
Red Bull (8.3 oz)	80
Water, caffeinated (Edge 2 O), (8 oz)	70
Anacin (2)	65
Bud Extra Beer, 10 oz	55
Propel Invigorating water	50
Jolt (8 oz)	48

## APPENDIX 40. Nutritional Facts on Essential (Omega) Fatty Acids

**Essential fatty acids** (EFAs) are fatty acids that are required in the human diet. They must be obtained from food because human cells have no biochemical pathways capable of producing them internally. There are two closely related families of EFAs: **omega-3 (Ω-3 or ω-3)** and **omega-6 (Ω-6 or ω-6)**. Only one substance in each of these families is truly essential, because, for example, the body can convert one ω-3 to another ω-3 but cannot create an ω-3 from scratch.

In the body essential fatty acids serve multiple functions. In each of these the balance between dietary ω-3 and ω-6 strongly affects function. They are modified to make the eicosanoids (affecting inflammation and many other cellular functions); the endogenous cannabinoids (affecting mood, behavior, and inflammation); the lipoxins from ω-6 EFAs and resolvins from ω-3 (in the presence of aspirin, down-regulating inflammation); the isofurans, isoprostanes, hepxoxilins, epoxyeicosatrienoic acids, and neuroprotectin D; and the lipid rafts (affecting cellular signaling). They also act on deoxyribonucleic acid (activating or inhibiting transcription factors for nuclear factor-κB [NFκB], a proinflammatory cytokine).

Between 1930 and 1950 arachidonic and linolenic acids were termed *essential* because each was more or less able to meet the growth requirements of rats given fat-free diets. Further research has shown that **human metabolism requires both fatty acids**. To some extent any ω-3 and any ω-6 can relieve the worst symptoms of fatty acid deficiency. However, in many people the ability to convert the ω-3

α-linolenic acid (ALA) to the ω-3 eicosapentaenoic (EPA) and docosahexaenoic acid (DHA) is only 5% efficient. Therefore it is important to incorporate the EPA and DHA directly into the diet usually as fish or a fish oil supplement. Particular fatty acids such as DHA are needed at critical life stages (e.g., infancy and lactation) and in some disease states.

The essential fatty acids are:

- ALA (18:3)-ω-3
- Linoleic acid (18:2)- ω-6

These two fatty acids cannot be synthesized by humans because humans lack the desaturase enzymes required for their production. They form the starting point for the creation of longer and more desaturated fatty acids, which are also referred to as long-chain polyunsaturates:

### ω-3 Fatty acids:

- EPA (20:5)
- DHA (22:6)
- ALA (18:)

### ω-6 Fatty acids:

- γ-Linolenic acid (GLA) (18:3)
- Dihomo-γ-linolenic acid (DGLA) (20:3)
- Arachidonic acid (AA) (20:4)

**ω-9 Fatty acids** are not essential in humans, because humans possess all the enzymes required for their synthesis.

### Adequate Intakes for ω-3 Fatty Acids for Children and Adults

Age (years)	Males and Females (g/day)	Pregnancy (g/day)	Lactation (g/day)
1-3	0.7	N/A	N/A
4-8	0.9	N/A	N/A
9-13	1.2 for boys; 1 for girls	N/A	N/A
14-18	1.6 for boys; 1.1 for girls	1.4	1.3
19+	1.6 for men; 1.1 for women	1.4	1.3

N/A, Not applicable.

### Adequate Intakes for ω-6 Fatty Acids for Children and Adults

Age (years)	Males and Females (g/day)	Pregnancy (g/day)	Lactation (g/day)
1-3	7	N/A	N/A
4-8	10	N/A	N/A
9-13	12 for boys; 10 for girls	N/A	N/A
14-18	16 for boys; 11 for girls	13	13
19+	17 for men; 12 for women	13	13

### Dietary Sources

Some of the food sources of ω-3 and ω-6 fatty acids are fish and shellfish, flaxseed (linseed), soya oil, canola (rapeseed) oil, hemp oil, chia seeds, pumpkin seeds, sunflower seeds, leafy vegetables, and walnuts.

EFAs play a part in many metabolic processes, and there is evidence to suggest that low levels of EFAs or the wrong balance of types among the EFAs may be a factor in a number of illnesses.

Plant sources of ω-3s do not contain EPA and DHA. This is thought to be the reason that absorption of EFAs is much greater from animal rather than plant sources.

EFA content of vegetable sources varies with cultivation conditions.

Animal sources vary widely, both with the animal's feed and that the EFA makeup varies markedly with fats from different body parts.

### Omega-3 Fatty Acids

There is some evidence that suggests that ω-3s may:

- Help lower elevated triglyceride levels. High triglyceride levels can contribute to coronary heart disease.
- Reduce the blood's tendency to clot, which may relate to the clogging that occurs with atherosclerosis.

- Reduce the inflammation involved in conditions such as rheumatoid arthritis.

- Improve symptoms of depression and other mental health disorders in some individuals.

Dietary sources of ω-3 fatty acids include fish oil and certain plant and nut oils. Fish oil contains both DHA and EPA, whereas some nuts (English walnuts) and vegetable oils (canola, soybean, flaxseed and linseed, olive) contain only the ω-3 ALA.

There is evidence from multiple large-scale population (epidemiologic) studies and randomized controlled trials that intake of recommended amounts of DHA and EPA in the form of fish or fish oil supplements lowers triglycerides; reduces the risk of death, heart attack, dangerous abnormal heart rhythms, and strokes in people with known cardiovascular disease; slows the buildup of atherosclerotic plaques ("hardening of the arteries"); and lowers blood pressure slightly. However, high doses may have harmful effects such as an increased risk of bleeding. Some species of fish carry a higher risk of environmental contamination such as with methyl mercury.

## APPENDIX 40. Nutritional Facts on Essential (Omega) Fatty Acids—cont'd

Common Food Sources of Omega-3 Fats		Fish or Other Food Source	Omega-3 Content in a 4-oz Serving
Omega-3 Fat	Food Source	Supplements*	
ALA	Ground flaxseed and walnuts and soybeans Flaxseed, walnut, soybean and canola oils, and nonhydrogenated canola and soy margarines	Cod liver oil Fish body oil Omega-3 fatty acid concentrate	800-100 mg/tsp 1200-1800 mg/tsp 250 mg/capsule
DHA and EPA	Mackerel, salmon, herring, trout and sardines, and other fish and shellfish Marine algae supplements		
Fish or Other Food Source	Omega-3 Content in a 4-oz Serving	Enhancing Intake of Omega-3 Fats	
English walnuts	6.8 g	<ul style="list-style-type: none"> <li>Eat fish at least two times each week.</li> <li>Include canned fish in your diet (examples: salmon, sardines, light tuna). Try sardines on toast.</li> <li>Add ground flaxseed to foods such as hot or cold cereal or yogurt. NOTE: Pregnant women should limit their intake of ground flaxseed to occasional use (not daily). Ground flaxseeds contain lignans. There is not enough information about their safety in pregnancy.</li> <li>Eat walnuts. Add walnuts to salads, cereals, baking (examples, muffins, cookies, breads) and pancakes.</li> <li>Have fresh or frozen soybeans (edamame) as a vegetable at meals.</li> <li>Use soybean oil or canola oil in salad dressings and recipes.</li> <li>Use nonhydrogenated margarine made from canola or soybean as a spread or in baking.</li> <li>Cook with ω-3 liquid eggs or eggs in the shell. Enjoy scrambled eggs or try a homemade egg sandwich.</li> <li>Use other ω-3 fortified products such as milk, yogurt, bread, and pasta.</li> <li>Substitute <math>\frac{1}{4}</math> cup ground flaxseed for <math>\frac{1}{4}</math> cup flour in bread, pizza dough, muffin, cookie, or meatloaf recipes.</li> <li>Replace 1 egg with 1 Tbsp ground flaxseed and 3 Tbsp water in recipes.</li> </ul>	
Chinook salmon	3.6 g		
Sockeye salmon	2.3 g		
Mackerel	1.8-2.6 g		
Herring	1.2-2.7 g		
Rainbow trout	1.0 g		
Wheat germ and oat germ	0.7-1.4 g		
Halibut	0.5-1.3 g		
White tuna	0.97 g		
Light tuna	0.35 g		
Whiting	0.9 g		
Spinach	0.9 g		
Flounder	0.6 g		
King crab	0.6 g		
Shrimp	0.5 g		
Tofu	0.4 g (probably much less in "lite" tofu)		
Clam	0.32 g		
Cod	0.3 g		
Scallop	0.23 g		

\*Exact omega-3 content varies per manufacturer. Check label.

## APPENDIX 41. Nutritional Facts on a High-Fiber Diet

This diet is a modification of the regular diet. The purpose of this diet is to decrease transit time through the intestine, promote more frequent bowel movements, and softer stools. This diet may be prescribed as a treatment for diverticulosis, irritable bowel syndrome, hemorrhoids, or constipation. It includes all the foods on a regular diet, with emphasis on the proper planning and selection of foods to increase the daily intake of fiber. Fluid intake should be increased. The

American Dietetic Association recommends that the average adult have a daily fiber intake of 20 to 35 g from a variety of sources. For children the child's age plus 5 g of fiber is recommended daily. In cases of severe constipation more fiber is recommended. Because of possible interactions with absorption of nutrients, regular intake of greater than 50 g of fiber per day is not recommended.

### Dietary Reference Intakes for Fiber for Children and Adults

Age (years)	Males and Females (g/day)	Pregnancy (g/day)	Lactation (g/day)
1-3	19	N/A	N/A
4-8	25	N/A	N/A
9-13	31 for boys; 26 for girls	N/A	N/A
14-18	38 for boys; 26 for girls	28	29
19+	38 for men; 25 for women	28	29

N/A, Not applicable.

Although numerous over-the-counter fiber supplements are available, food sources provide other nutrients and are the preferred method of increasing dietary fiber. Adequate liquid consumption (at least eight 8-oz glasses per day) is recommended. Fiber should be added to the diet slowly because of possible cramps, bloating, and diarrhea with a

sudden fiber increase. Maximum therapeutic benefits of fiber are obtained after several months of compliance. There are two components of dietary fiber, each providing health benefits: insoluble and soluble.

*Continued*

**APPENDIX 41.** Nutritional Facts on a High-Fiber Diet—cont'd**Types of Dietary Fiber**

Type of Fiber	Components of Cells	Food Sources	Health Benefits
Soluble fibers	Gums, mucilages, pectin, certain hemicelluloses	Vegetables, fruits, barley; legumes, oats, and oat-bran	Decrease total blood cholesterol. Guard against diabetes. Prevent constipation. May help manage irritable bowel syndrome. May protect against colon cancer and gallstones. May prevent diverticular disease. Prevents constipation. May delay glucose absorption (probably insignificant). May increase satiety and therefore assist with weight loss. Lower cholesterol. May protect against colon cancer.
Insoluble fibers	Cellulose, lignin, some hemicelluloses	Whole-wheat products, wheat and corn bran, and many vegetables (including cauliflower, green beans, potatoes, and skins of root vegetables)	

**Guidelines for High-Fiber Diet**

1. Increase consumption of whole-grain breads, cereals, flours, and other whole-grain productions to 6 to 11 servings daily.
2. Increase consumption of vegetables, legumes and fruits, nuts, and edible seeds to 5 to 8 servings daily.
3. Consume high-fiber cereals, granolas, and legumes as needed to bring fiber intake to 25 g or more daily.
4. Increase consumption of fluids to at least 2 L (or approximately 2 qt) daily.
5. For a high-fiber diet of approximately 24 g of dietary fiber: use 12 or more servings of the foods from the groups below (each food contains approximately 2 g of dietary fiber). For example,  $\frac{1}{2}$  cup of baked beans (8 Tbsp) would count as 4 servings.

**Each of these foods in this amount contains 2 g of dietary fiber:**

Apple, 1 small	Strawberries, $\frac{1}{2}$ cup
Orange, 1 small	Pear, $\frac{1}{2}$ small
Banana, 1 small	Cherries, 10 large
Peach, 1 medium	Plums, 2 small
Whole-wheat bread, 1 slice	Oatmeal, dry, 3 Tbsp
All Bran, 1 Tbsp	Shredded wheat, $\frac{1}{2}$ biscuit
Rye bread, 1 slice	Wheat bran, 1 tsp
Corn flakes, $\frac{1}{2}$ cup	Grape-nuts, 3 Tbsp
Cracked wheat bread, 1 slice	Puffed wheat, $1\frac{1}{3}$ cup
Broccoli, $\frac{1}{2}$ stalk	Potato, 2-in diameter
Lettuce, raw, 2 cups	Celery, 1 cup
Brussels sprouts, 4	Tomato, raw, 1 medium
Green beans, $\frac{1}{2}$ cup	Corn on the cob, 2 in
Carrots, $\frac{1}{2}$ cup	Baked beans, canned, 2 Tbsp

**Selected Food Sources of Fiber**

Food	Grams per Serving	% Daily Value*
Navy beans, cooked, $\frac{1}{2}$ cup	9.5	38
Bran ready-to-eat cereal (100%), $\frac{1}{2}$ cup	8.8	35
Kidney beans, canned, $\frac{1}{2}$ cup	8.2	33
Split peas, cooked, $\frac{1}{2}$ cup	8.1	32
Lentils, cooked, $\frac{1}{2}$ cup	7.8	31
Black beans, cooked, $\frac{1}{2}$ cup	7.5	30
Pinto beans, cooked, $\frac{1}{2}$ cup	7.7	31
Lima beans, cooked, $\frac{1}{2}$ cup	6.6	26
Artichoke, globe, cooked, 1 each	6.5	26
White beans, canned, $\frac{1}{2}$ cup	6.3	25
Chickpeas, cooked, $\frac{1}{2}$ cup	6.2	24
Great northern beans, cooked, $\frac{1}{2}$ cup	6.2	24
Cowpeas, cooked, $\frac{1}{2}$ cup	5.6	22
Soybeans, mature, cooked, $\frac{1}{2}$ cup	5.2	21
Bran ready-to-eat cereals, various, 1 oz	2.6-5.0	10-20
Crackers, rye wafers, plain, 2 wafers	5.0	20
Sweet potato, baked, with peel, 1 medium (146 g)	4.8	19
Asian pear, raw, 1 small	4.4	18
Green peas, cooked, $\frac{1}{2}$ cup	4.4	18
Whole-wheat English muffin, 1 each	4.4	18
Pear, raw, 1 small	4.3	17
Bulgur, cooked, $\frac{1}{2}$ cup	4.1	16

\*Daily values (DVs) are reference numbers based on the recommended dietary allowance. They were developed to help consumers determine if a food contains a lot or a little of a specific nutrient. The DV for fiber is 25 g. The percent DV (%DV) listed on the Nutrition Facts panel of food labels states the percentage of the DV provided in 1 serving. %DVs are based on a 2000-calorie diet.

Food Sources of Dietary Fiber ranked by grams of dietary fiber per standard amount. (All are  $\geq 10\%$  of adequate intake for adult women, which is 25 g/day.)

## APPENDIX 41. Nutritional Facts on a High-Fiber Diet—cont'd

### Selected Food Sources of Fiber

Food	Grams per Serving	% Daily Value*
Mixed vegetables, cooked, $\frac{1}{2}$ cup	4.0	16
Raspberries, raw, $\frac{1}{2}$ cup	4.0	16
Sweet potato, boiled, no peel, 1 medium (156 g)	3.9	15.5
Blackberries, raw, $\frac{1}{2}$ cup	3.8	15
Potato, baked, with skin, 1 medium	3.8	15
Soybeans, green, cooked, $\frac{1}{2}$ cup	3.8	15
Stewed prunes, $\frac{1}{2}$ cup	3.8	15
Figs, dried, $\frac{1}{4}$ cup	3.7	14.5
Dates, $\frac{1}{4}$ cup	3.6	14
Oat bran, raw, $\frac{1}{4}$ cup	3.6	14
Pumpkin, canned, $\frac{1}{2}$ cup	3.6	14
Spinach, frozen, cooked, $\frac{1}{2}$ cup	3.5	14
Shredded wheat ready-to-eat cereals, various, ≈1 oz	2.8-3.4	11-13
Almonds, 1 oz	3.3	13
Apple with skin, raw, 1 medium	3.3	13
Brussels sprouts, frozen, cooked, $\frac{1}{2}$ cup	3.2	13
Whole-wheat spaghetti, cooked, $\frac{1}{2}$ cup	3.1	12
Banana, 1 medium	3.1	12
Orange, raw, 1 medium	3.1	12
Oat bran muffin, 1 small	3.0	12
Guava, 1 medium	3.0	12
Pearled barley, cooked, $\frac{1}{2}$ cup	3.0	12
Sauerkraut, canned, solids, and liquids, $\frac{1}{2}$ cup	3.0	12
Tomato paste, $\frac{1}{4}$ cup	2.9	11.5
Winter squash, cooked, $\frac{1}{2}$ cup	2.9	11.5
Broccoli, cooked, $\frac{1}{2}$ cup	2.8	11
Parsnips, cooked, chopped, $\frac{1}{2}$ cup	2.8	11
Turnip greens, cooked, $\frac{1}{2}$ cup	2.5	10
Collards, cooked, $\frac{1}{2}$ cup	2.7	11
Okra, frozen, cooked, $\frac{1}{2}$ cup	2.6	10
Peas, edible-podded, cooked, $\frac{1}{2}$ cup	2.5	10

### High-Fiber Meal Plan

Breakfast	Lunch	Dinner
1 orange	3-oz boneless, skinless chicken breast	1 cup spaghetti with meat sauce
$\frac{3}{4}$ cup raisin bran	$\frac{1}{2}$ cup broccoli	1 cup tossed salad with assorted vegetables and $\frac{1}{4}$ cup chickpeas*
2 slices whole wheat toast	$\frac{1}{2}$ cup long grain and wild rice	1 slice Italian bread
2 tsp margarine	1 whole wheat roll	$\frac{1}{2}$ cup apple crisp
1 cup skim milk	$\frac{1}{2}$ cup chocolate pudding	2 tsp margarine
1 cup coffee	$\frac{1}{2}$ Tbsp whipped topping	1 cup skim milk
2 tsp sugar	2 tsp margarine	1 cup coffee
	1 cup iced tea	$\frac{1}{4}$ tsp salt
	$\frac{1}{4}$ tsp salt	$\frac{1}{4}$ tsp pepper
	$\frac{1}{4}$ tsp pepper	2 tsp sugar
	2 tsp sugar	

### Nutritional Analysis

Kilocalories: 2074  
 Protein: 84 g  
 Fat: 52 g  
 Carbohydrate: 313 g  
 Sodium: 4647 mg  
 Potassium: 3706 mg  
 Fiber: 28 g

\*Fiber content may be higher, depending on vegetables selected for salad.

## APPENDIX 42. Nutritional Facts on Fluid and Hydration

Adequate **hydration** is essential for life. Body water is necessary to regulate body temperature, transport nutrients, moisten body tissues, compose body fluids, and make waste products soluble for excretion.

**Principles:** As the most plentiful substance in the human body, water is also the most plentiful nutrient in the diet. The amount of water recommended for an individual varies with age, activity, medical condition, and physical condition. The water in juice, tea, milk, decaffeinated coffee, and carbonated beverages contributes the majority of water in the diet. Solid foods also contribute water to the diet but usually are not counted in the amount of water provided per day.

Water deficiency, or **dehydration**, is characterized by dark urine; decreased skin turgor; dry mouth, lips, and mucous membranes; headache; a coated, wrinkled tongue; dry or sunken eyes; weight loss; a lowered body temperature; and increased serum sodium, albumin, blood urea nitrogen (BUN), and creatinine values. Dehydration may be caused by inadequate intake in relation to fluid requirements or excessive fluid losses caused by fever, increased urine output, diarrhea,

draining wounds, ostomy output, fistulas, environmental temperature, or vomiting. Concentrated or high-protein tube feeding formulas may increase the water requirement.

Thirst is often the first noticed sign of the need for more water. However, athletes or workers exercising or working hard in hot climates may be significantly dehydrated before they realize they are thirsty. In these situations they should be drinking at regular intervals; they may not be able to rely on thirst to determine their need to drink.

Water excess or **overhydration** is rare and may be the result of inadequate output or excessive intake. Overhydration is characterized by increased blood pressure; decreased pulse rate; edema; and decreased serum sodium, potassium, albumin, BUN, and creatinine values. Fluid restrictions may be necessary for certain medical conditions such as kidney or cardiac disease. For those on fluid restrictions, the fluid needs should be calculated on an individual basis. The usual diet provides approximately 1080 mL (36 oz), a little more than a quart of fluid per day.

### Approximate Fluid Content of Common Foods

Food	Fluid Ounces	Household Measure	Metric Measure
Juice	2	¼ cup	60 mL
	3	⅓ cup	90 mL
	4	½ cup	120 mL
	8	1 cup	240 mL
	6	⅔ cup	180 mL
Coffee, tea, decaffeinated coffee	6	⅔ cup	180 mL
Gelatin	4	½ cup	120 mL
Ice cream, sherbet	3	⅓ cup	90 mL
Soup	6	⅔ cup	180 mL
Liquid coffee creamer	1	2 Tbsp	30 mL

### Estimating Daily Fluid Requirements for Healthy Individuals

Children	Body Weight	Daily Fluid Requirement
Infants		140 to 150 mL/kg
Children		
Method 1		50 to 60 mL/kg
Method 2	3 to 10 kg of body weight	100 mL/kg
	11 to 20 kg of body weight	1000 mL + 50 mL/kg >10
	More than 20 kg	1500 mL + 20 mL/kg >20
Adults*		
Method 1	30 to 35 mL per weight in kilograms	
Method 2	1 mL fluid per calorie consumed	
Method 3	First 10 kg of body weight	100 mL/kg
	Second 10 kg of body weight	+50 mL/kg
	Remaining kg of body weight (age <50)	+20 mL/kg
	Remaining kg of body weight (age >50)	+15 mL/kg
Method 4	Age in years	
	16-30 (active)	40 mL/kg
	20-55	35 mL/kg
	55-75	30 mL/kg
	>75	25 mL/kg

From the California Diet Manual, ©2003, State of California Department of Developmental Services, revised 2004.

\*The 1 mL of fluid per calorie method should be used with caution because it will underestimate the fluid needs of those with low-calorie needs. Persons who are significantly obese may best be evaluated by Method 3 because it adjusts for high body weight.

Note: 3 oz is approximately  $\frac{1}{3}$  cup; 6 oz is approximately  $\frac{2}{3}$  cup.

## APPENDIX 43. Glycemic Index and Glycemic Load of Selected Foods\*

	GI	GL		GI	GL		GI	GL
<b>Breakfast Cereals</b>			<b>Vegetables</b>			<b>Custard</b>	43	7

## APPENDIX 44. Nutritional Facts on a High-Protein Diet

The high-protein diet is designed for individuals requiring increased protein in addition to their normal diet. This diet provides additional high-quality protein, primarily from milk, eggs, cheese, soy, and meat sources. An individual's protein intake may be increased to 100 g of protein per day, or 1.25 up to 2 g/kg. Indications for use are the presence of pressure ulcers, surgery, infection, or malnutrition. Contraindications include hepatic coma and renal insufficiency. Patients on this diet may have loss of or poor appetite; therefore six feedings per day may improve patient adherence.

**Adequacy:** The high-protein diet is adequate in all nutrients and exceeds the dietary reference intake for protein.

### Minimum Portions to Achieve 100 g of Protein

- 2-3 Cups or more (8 oz each) fortified milk or substitute
- 3-4 Servings (2-3 oz servings) meat or meat substitute
- 3-4 Servings fruits and vegetables (1 vitamin C-rich source daily such as 1 citrus fruit, 1 carotenoid source such as 1 dark green or yellow vegetable)
- 3-4 Servings or more of whole grain or enriched breads and cereals
- Other foods are included to provide adequate calories.

### Special Notes

1. Nonfat dry milk may be added to cooked foods to increase protein intake. One quarter cup powdered milk is equivalent to 1 cup fluid milk. Nonfat dry milk can be added to hot cereal, cream soups, and casseroles.

2. Supplemental high-protein feedings may be required if the patient has a poor appetite.
3. One fluid cup (8 oz) commercial eggnog contains 15 g of protein, almost twice as much protein as 1 fluid cup (8 oz) of milk. This is a very good snack for use in a high-protein diet.

### Suggested Meal Pattern: High-Protein

Breakfast	Noon Meal	Evening Meal
½ cup fruit or juice	3 oz meat or substitute	3 oz meat or substitute
½ cup cereal	½ cup potato or substitute	½ cup potato or substitute
2 eggs	½ cup veg and/or	½ cup veg and/or
1 serving bread	½ cup veg and/or	½ cup veg and/or
1 tsp margarine	½ - ¾ cup salad	½ - ¾ cup salad
1 cup (8 oz) milk	Salad dressing	Salad dressing
Coffee or tea	1 serving bread	1 serving bread
	1 tsp margarine	1 tsp margarine
	½ cup fruit or dessert	½ cup fruit or dessert
	1 cup (8 oz) milk	1 cup (8 oz) milk
<b>AM Snack</b>	<b>PM Snack</b>	<b>Bedtime Snack</b>
8 oz. eggnog	Cheese or crackers	Milk and sandwich

## APPENDIX 45. Nutritional Facts on Vegetarian Eating

These diets are designed for those who prefer vegetarian eating for religious, ecologic, or personal reasons. Because of the variations in vegetarian diets, it is recommended that the dietitian work closely with the patient and his or her family in establishing a diet pattern. Vegetarian diets are usually classified into one of the following three types:

1. Lacto-ovo-vegetarian is a modification of the diet, which restricts all dietary sources of animal protein except dairy products and eggs. This is the most common type of vegetarian diet and is the easiest of the vegetarian diets to prepare.
2. Lacto-vegetarian is a modification of the diet, which restricts all dietary sources of animal protein except dairy products.
3. Strict vegetarian (vegan diet) is a modification of the diet, which restricts all dietary sources of animal protein.

**Adequacy:** the lacto-ovo and lacto-vegetarian diets require careful planning to be adequate in all nutrients to meet the dietary reference intakes. The strict vegetarian diet (vegan diet) may be deficient in protein, zinc, calcium, and vitamins D and vitamin B<sub>12</sub>; therefore supplements or fortified foods are recommended.

**Protein:** No foods are prepared with meat-based broth. Substitute soy-based and vegetable broths.

The following foods provide approximately the same amount of protein as does 1 oz of meat (7 g of protein):

¼ cup cottage cheese	½ cup legumes, cooked
1 cup regular or soy milk	¼ cup soy beans
1 oz cheese	1 oz processed soy protein
½ cup mixed nuts	½ cup tofu (soy cheese)
1 egg	¾ cup yogurt
2 Tbsp peanut butter	

Proper protein combinations combine the essential amino acids to provide high-quality proteins, but they do not have to be at the same meal. The following list provides some of the combinations:

### Grains

- Rice with legumes
- Rice cooked in milk
- Corn with legumes
- Macaroni and cheese
- Whole-wheat bread and cheese
- Whole-grain breakfast cereal with milk
- Whole-wheat toast with poached egg

### Nuts and Seeds

- Peanut butter sandwich with milk
- Sesame seeds with beans as in hummus

### Legumes

- Baked beans with whole-wheat bread
- Legumes with rice
- Split pea soup and whole-wheat bread
- Soy beans with rice and wheat
- Soy beans with corn and milk
- Soy yogurt with granola

### Vegetables

- Lima beans, peas, Brussels sprouts, cauliflower or broccoli with sesame seeds, Brazil nuts, or mushrooms

**Calcium:** All vegetarians, especially young women, should ensure adequate calcium intake for development and maintenance of strong bones. In place of dairy products, choose abundant amounts of dark, leafy greens (e.g., kale, mustard and turnip greens, collards); bok choy; broccoli; legumes; tofu processed with calcium; dried figs; sunflower seeds; and calcium-fortified cereals and juice. The following foods provide approximately the same amount of calcium as 1 cup of milk (approximately 300 mg).

1 cup calcium-fortified soy milk	3 cups cooked dried beans
1 ½ cups sunflower seeds	1 cup almonds
1 cup collards, cooked	3 pieces enriched cornbread

## APPENDIX 45. Nutritional Facts on Vegetarian Eating—cont'd

**Iron:** Iron deficiency rates are similar between vegetarians and nonvegetarians. When consumed along with foods rich in vitamin C, plant sources of iron are better absorbed. High-iron foods include legumes, dark green vegetables (i.e., spinach and beet greens), dried fruits; prune juice, blackstrap molasses, pumpkin seeds, soy nuts, and iron-fortified breads and cereals.

**Vitamin B12:** Found only in animal foods, vitamin B12 is not a nutrient of great concern for vegetarians who regularly consume eggs or dairy products (lacto-ovo-vegetarians). Vegans should include vitamin B12-fortified foods such as fortified soy milk and commercial breakfast cereals, or a B12 supplement in their diets. Vitamin B12 is also found in Brewer's yeast.

**Vitamin D:** In the United States the primary source of vitamin D is dairy products, most of which are fortified with vitamin D.

However, cheese and yogurt do not have to be made from vitamin D-fortified milk. The other main source results from sunlight exposure, causing vitamin D to be synthesized in the skin. If dairy products are not consumed and direct sunlight exposure is limited, supplementation is warranted. Foods containing vitamin D include fortified cow's milk, soy milk, rice milk, or nut milk.

Supplementation is needed for individuals who do not consume milk products or who spend little time in the sun.

**Zinc:** Because zinc is found in animal foods, the vegetarian diet may be limited. The following foods can be included in the diet to increase the needed amount of zinc:

- Wheat germ
- Nuts
- Dried beans

### Minimum Portions to Be Included Daily

Food Categories	Recommended Daily Servings	Recommended Serving Sizes
Breads, cereals, rice, and pasta	6 or more	1 slice bread 1 oz ready to eat cereal, calcium fortified* $\frac{1}{2}$ cup cooked cereal, rice, or pasta
Vegetables	4 or more	1 cup raw leafy vegetables, $\frac{1}{2}$ cup cooked vegetables, calcium rich—1 cup cooked, 2 cups raw: bok choy,* okra,* broccoli,* collards,* kale,* Chinese cabbage,* mustard greens*
Fruits	2 or more	$\frac{1}{2}$ cup vegetable juice fortified* 1 medium piece of fruit $\frac{1}{2}$ cup chopped, cooked, or canned fruit, figs (5)* $\frac{1}{2}$ cup fruit juice, fortified*
Calcium-rich foods	8 or more	1 cup milk, yogurt, $\frac{1}{2}$ cup fortified soy milk $\frac{1}{4}$ oz natural cheese 2 oz process cheese
Legumes and meat substitutes	5	$\frac{1}{2}$ cup cooked dry beans, soybeans* or peas, $\frac{1}{2}$ cup soy nuts* 1 egg or 2 egg whites (optional) $\frac{1}{4}$ cup nuts or seeds, $\frac{1}{4}$ cup almonds* $\frac{1}{2}$ cup Tempeh or calcium-set tofu* 2 Tbsp almond butter or sesame tahini,* 2 Tbsp peanut butter
Fats, sweets, and alcohol	Use sparingly	

\*Calcium-rich foods.

### Special Notes

**Pregnancy and Lactation:** Well-planned vegan and lacto-ovo-vegetarian eating patterns adequately provide for the nutritional needs of pregnant and lactating women (American Dietetic Association, 2003). Folate supplements are recommended for all pregnant women, including vegetarians. Vegans must ensure daily intake of 2 mcg of vitamin B12 daily during pregnancy and 2.6 mcg during lactation, whether through supplements or fortified foods. Women with limited sun exposure should include vitamin D-fortified foods. Caution should be used with vitamin D supplementation because excess vitamin D can cause fetal abnormalities.

**Infants, Children, and Adolescents:** According to the American Dietetic Association (2003), well-planned vegan and lacto-ovo-vegetarian eating patterns adequately provide for the nutritional needs of infants, children, and adolescents. Because of the high bulk of low-fat vegetarian eating patterns, it may be difficult for children and adolescents to consume enough food to provide for their energy needs. Frequent meals and snacks with nutrient-dense foods can help meet energy and nutrient needs. If sun exposure is limited, vitamin D-fortified foods or supplements may be used. Vegan children should include a reliable source of vitamin B12 in their diets. To provide for growth, calcium, iron, and zinc intakes deserve special attention. It is recommended that parents of vegetarian infants and youth consult a registered dietitian with expertise in the vegetarian eating pattern.

## APPENDIX 46. Nutritional Facts on Folic Acid, Vitamin B<sub>6</sub>, and Vitamin B<sub>12</sub>

Folate is a water-soluble B vitamin that occurs naturally in food. Folic acid is the synthetic form of folate that is found in supplements and added to fortified foods. Folate or folic acid helps produce and maintain new cells, which is especially important during periods of rapid cell division and growth such as infancy, adolescence, and pregnancy. Folate is needed to make deoxyribonucleic acid (DNA) and

ribonucleic acid, the building blocks of cells. It also helps prevent changes to DNA that may lead to cancer. Both adults and children need folate to make normal red blood cells and prevent anemia. Folate is also essential for the metabolism of homocysteine and helps maintain normal levels of this amino acid.

### Dietary Reference Intakes for Folate for Children and Adults

Age (years)	Males and Females (mcg/day)	Pregnancy (mcg/day)	Lactation (mcg/day)
1-3	150	N/A	N/A
4-8	200	N/A	N/A
9-13	300	N/A	N/A
14-18	400	600	500
19+	400	600	500

N/A, Not applicable.

### Selected Food Sources of Folate and Folic Acid

Food	Micrograms per Serving	% Daily Value*
Breakfast cereals fortified with 100% of the DV, $\frac{3}{4}$ cup <sup>†</sup>	400	100
Beef liver, cooked, braised, 3 oz	185	45
Cowpeas (blackeyes), immature, cooked, boiled, $\frac{1}{2}$ cup	105	25
Breakfast cereals, fortified with 25% of the DV, $\frac{3}{4}$ cup <sup>†</sup>	100	25
Spinach, frozen, cooked, boiled, $\frac{1}{2}$ cup	100	25
Great Northern beans, boiled, $\frac{1}{2}$ cup	90	20
Asparagus, boiled, 4 spears	85	20
Rice, white, long-grain, parboiled, enriched, cooked, $\frac{1}{2}$ cup <sup>†</sup>	65	15
Vegetarian baked beans, canned, 1 cup	60	15
Spinach, raw, 1 cup	60	15
Green peas, frozen, boiled, $\frac{1}{2}$ cup	50	15
Broccoli, chopped, frozen, cooked, $\frac{1}{2}$ cup	50	15
Egg noodles, cooked, enriched, $\frac{1}{2}$ cup <sup>†</sup>	50	15
Broccoli, raw, 2 spears (each 5 in long)	45	10
Avocado, raw, all varieties, sliced, $\frac{1}{2}$ cup sliced	45	10
Peanuts, all types, dry roasted, 1 oz	40	10
Lettuce, Romaine, shredded, $\frac{1}{2}$ cup	40	10
Wheat germ, crude, 2 Tbsp	40	10
Tomato juice, canned, 6 oz	35	10
Orange juice, chilled, includes concentrate, $\frac{3}{4}$ cup	35	10
Turnip greens, frozen, cooked, boiled, $\frac{1}{2}$ cup	30	8
Orange, all commercial varieties, fresh, 1 small	30	8
Bread, white, 1 slice <sup>†</sup>	25	6
Bread, whole wheat, 1 slice <sup>†</sup>	25	6
Egg, whole, raw, fresh, 1 large	25	6
Cantaloupe, raw, $\frac{1}{4}$ medium	25	6
Papaya, raw, $\frac{1}{2}$ cup cubes	25	6
Banana, raw, 1 medium	20	6

DV, Daily value.

\*DVs are reference numbers based on the recommended dietary allowance. They were developed to help consumers determine if a food contains a lot or a little of a specific nutrient. The DV for folate is 400 mcg. The %DV listed on the Nutrition Facts panel of food labels states the percentage of the DV provided in one serving.

<sup>†</sup>Fortified with folic acid as part of the Folate Fortification Program.

### Vitamin B<sub>6</sub>

Vitamin B<sub>6</sub> is a water-soluble vitamin that exists in three major chemical forms: pyridoxine, pyridoxal, and pyridoxamine and performs a wide variety of functions in the body. It is needed for more than 100 enzymes involved in protein metabolism and is essential for red blood cell metabolism. The nervous and immune systems need vitamin B<sub>6</sub> to function efficiently, and it is also needed for the conversion of tryptophan (an amino acid) to niacin. A vitamin

B<sub>6</sub> deficiency can result in a form of anemia that is similar to iron deficiency anemia.

Through its involvement in protein metabolism and cellular growth, vitamin B<sub>6</sub> is important to the immune system. It helps maintain the health of lymphoid organs (thymus, spleen, and lymph nodes) that make white blood cells. It is also important for maintaining normal blood glucose levels.

*Continued*

**APPENDIX 46.** Nutritional Facts on Folic Acid, Vitamin B<sub>6</sub>, and Vitamin B<sub>12</sub>—cont'd**Dietary Reference Intakes for Vitamin B<sub>6</sub> for Children and Adults**

Age (years)	Males and Females (mg/day)	Pregnancy (mg/day)	Lactation (mg/day)
1-3	0.5	N/A	N/A
4-8	0.6	N/A	N/A

Salmon, Sockeye, cooked, 3 oz	0.19	10%
Tuna, canned in water, drained solids, 3 oz	0.18	10%
Wheat bran, crude or unprocessed, $\frac{1}{4}$ cup	0.18	10%
Peanut butter, smooth, 2 Tbsp	0.15	8%
Walnuts, English or Persian, 1 oz	0.15	8%
Soybeans, green, boiled, drained, $\frac{1}{2}$ cup	0.05	2%
Lima beans, frozen, cooked, drained, $\frac{1}{2}$ cup	0.10	6%

\*Daily values (DVs) are reference numbers based on the recommended dietary allowance. They were developed to help consumers determine if a food contains a lot or a little of a specific nutrient. The DV for vitamin B<sub>6</sub> is 2 mg. The %DV listed on the Nutrition Facts panel of food labels states the percentage of the DV provided in one serving.

**Vitamin B<sub>12</sub>**

Along with folate and vitamin B<sub>6</sub>, vitamin B<sub>12</sub> is helpful in lowering the level of the amino acid homocysteine in the blood. It has been hypothesized that at high levels homocysteine might damage coronary arteries or make it easier for blood-clotting cells to clump together and form a clot. This could increase risks for a heart attack or stroke.

Vitamin B<sub>12</sub> is a member of the vitamin B complex. It contains cobalt; thus it is also known as cobalamin. It is exclusively synthesized by bacteria and is found primarily in meat, eggs, and dairy products. There has been considerable research into proposed plant sources of vitamin B<sub>12</sub>. Fermented soy products, seaweeds, and algae (*spirulina*) have all been suggested as containing significant B<sub>12</sub>. However, the

present consensus is that any B<sub>12</sub> present in plant foods is likely to be unavailable to humans; thus these foods should not be relied on as safe sources. Many vegan foods are supplemented with B<sub>12</sub>.

Vitamin B<sub>12</sub> is necessary for the synthesis of red blood cells, the maintenance of the nervous system, and growth and development in children. Deficiency can cause anemia. Vitamin B<sub>12</sub> neuropathy, involving the degeneration of nerve fibers and irreversible neurologic damage, can also occur. Vitamin B<sub>12</sub> can be stored in small amounts by the body. Proper vitamin B<sub>12</sub> absorption requires the presence of intrinsic factor, which tends to diminish with aging. Total body store is 2 to 5 mg in adults. Approximately 80% of this is stored in the liver.

**Dietary Reference Intakes for Vitamin B<sub>12</sub> for Children and Adults**

Age (years)	Males and Females (mcg/day)	Pregnancy (mcg/day)	Lactation (mcg/day)
1-3	0.9	N/A	N/A
4-8	1.2	N/A	N/A

## APPENDIX 46. Nutritional Facts on Folic Acid, Vitamin B<sub>6</sub>, and Vitamin B<sub>12</sub>—cont'd

### Selected Food Sources of Vitamin B<sub>12</sub>

Food	Micrograms per Serving	% Daily Value*
Mollusks, clam, mixed species, cooked, 3 oz	84.1	1400
Liver, beef, braised, 1 slice	47.9	780
Fortified breakfast cereals (100% fortified), $\frac{3}{4}$ cup	6.0	100
Trout, rainbow, wild, cooked, 3 oz	5.4	90
Salmon, sockeye, cooked, 3 oz	4.9	80
Trout, rainbow, farmed, cooked, 3 oz	4.2	50
Beef, top sirloin, lean, choice, broiled, 3 oz	2.4	40
Fast food, cheeseburger, regular, double patty and bun, 1 sandwich	1.9	30
Fast food, taco, 1 large	1.6	25
Fortified breakfast cereals (25% fortified), $\frac{3}{4}$ cup	1.5	25
Yogurt, plain, skim, with 13 g of protein per cup, 1 cup	1.4	25
Haddock, cooked, 3 oz	1.2	20
Clams, breaded and fried, $\frac{3}{4}$ cup	1.1	20
Tuna, white, canned in water, drained solids, 3 oz	1.0	15
Milk, 1 cup	0.9	15
Pork, cured, ham, lean only, canned, roasted, 3 oz	0.6	10
Egg, whole, hard boiled, 1	0.6	10
American pasteurized cheese food, 1 oz	0.3	6
Chicken, breast, meat only, roasted, $\frac{1}{2}$ breast	0.3	6

\*Daily values (DVs) are reference numbers based on the recommended dietary allowance. They were developed to help consumers determine if a food contains a lot or little of a specific nutrient. The DV for vitamin B<sub>12</sub> is 6 mcg. The %DV listed on the Nutrition Facts panel of food labels states the percentage of the DV provided in one serving.

## APPENDIX 47. Nutritional Facts on Vitamin A and Carotenoids

Vitamin A includes a group of compounds that affect vision, bone growth, reproduction, cell division, immunity, healthy surface linings of the respiratory tract, and mucous membranes. There are two categories of vitamin A, depending on whether the food source is an animal or a plant. Vitamin A found in foods that come from animals is called *preformed vitamin A* and is absorbed as retinol. Sources include liver, whole milk, and some fortified food products. In the body retinol can be made into retinal and retinoic acid (other active forms of vitamin A). Vitamin A deficiency rarely occurs in the United States, but vitamin A is needed for children with measles, infection, or eye disease in communities where vitamin A deficiency is a serious problem. Fat malabsorption can result in diarrhea and prevent normal absorption of

vitamin A; this may result in vitamin A deficiency in celiac disease, Crohn's disease, and pancreatic disorders. The best absorbed form of vitamin A is in the oil form such as in cod liver oil.

Plant sources of vitamin A provide the provitamin A, called *carotenoids*. They can be made into retinol in the body and then to the other active forms of vitamin A. In the United States approximately 26% to 34% of vitamin A consumed is in the form of provitamin A carotenoids. Common provitamin A carotenoids found in plants give them color and are  $\beta$ -carotene,  $\alpha$ -carotene, and  $\beta$ -cryptoxanthin. Among these,  $\beta$ -carotene is most efficiently made into retinol. The darker the color of a fruit or vegetable, the greater is its carotenoid content.

### Dietary Reference Intakes for Vitamin A for Children and Adults

Age (years)	Males and Females (mcg RAEs/day)	Pregnancy (mcg RAEs/day)	Lactation (mcg RAEs/day)
1-3	300	N/A	N/A
4-8	400	N/A	N/A
9-13	600	N/A	N/A
14-18	900 for boys; 700 for girls	1200	750
19+	900 for men; 700 for women	770	1300

N/A, Not applicable; RAE, Retinol activity equivalent.

1 RAE = 1 mcg of retinol = 12 mg of  $\beta$ -carotene = 3.33 IU of vitamin A on a label.

### Food Sources of Vitamin A

Vitamin A in foods is expressed as micrograms of retinol activity equivalents (RAEs) of vitamin A per standard amount, but it is also stated as IU = 0.33 mcg RAEs. (All are  $\geq 20\%$  of the recommended dietary allowance for adult men, which is 900 mcg RAE/day.)

### Selected Animal Sources of Vitamin A

Food	Vitamin A (IU)	% Daily Value
Liver, beef, cooked, 3 oz	27,185	545
Liver, chicken, cooked, 3 oz	12,325	245
Milk, fortified skim, 1 cup	500	10
Cheese, cheddar, 1 oz	284	6
Milk, whole (3.25% fat), 1 cup	249	5
Egg substitute, $\frac{1}{4}$ cup	226	5

Continued

**APPENDIX 47.** Nutritional Facts on Vitamin A and Carotenoids—cont'd**Selected Plant Sources of Vitamin A (from β-Carotene)**

Food	Vitamin A (IU)	% Daily Value*
Carrot juice, canned, ½ cup	22,567	450
Carrots, boiled, ½ cup slices	13,418	270
Spinach, frozen, boiled, ½ cup	11,458	230
Kale, frozen, boiled, ½ cup	9558	190
Carrots, 1 raw (7½ in)	8666	175
Vegetable soup, canned, chunky, ready-to-serve, 1 cup	5820	115

Peas, frozen, boiled, ½ cup	1050	20
Tomato juice, canned, 6 oz	819	15
Peaches, canned, juice pack, ½ cup halves or slices	473	10
Peach, 1 medium	319	6
Pepper, sweet, red, raw, 1 ring (3 inches diameter by ¼ inch thick)	313	6

\*Daily values (DVs) are reference numbers based on the recommended dietary allowances. They were developed to help consumers determine if a food contains a lot or a little of a nutrient. The DV for vitamin A is 5000 IU. Most food labels do not list vitamin A content. The %DV column in this table indicates the percentage of the DV provided in one serving. A food providing 5% or less of the DV is a low source, whereas a food that provides 10% to 19% of the DV is a good source. A food that provides 20% or more of the DV is high in that nutrient. It is important to remember that foods that provide lower percentages of the DV also contribute to a healthful diet.

Another way to summarize important foods is through retinol equivalents.

Food	Vitamin A (mcg RAEs)	Calories
Organ meats (liver, giblets), various, cooked, 3 oz <sup>†</sup>	1490-9126	134-235

Table from Sommerburg O et al: Fruits and vegetables that are sources for lutein and zeaxanthin: the macular pigment in human eyes, Br J Ophthalmol 82:907, 1998.

The content of the major carotenoids are given in mole%. The amounts of the carotenoids were shown in seven major groups, as neoxanthins and violaxanthins (neoxanthin, violaxanthin, and their related isomers, lutein 5, 6 epoxide), lutein, zeaxanthin, cryptoxanthins ( $\alpha$ -cryptoxanthin,  $\beta$ -cryptoxanthins, and related isomers), lycopenes (lycopene and related isomers),  $\beta$ -carotene (all *trans*  $\beta$ -carotene and *cis* isomers), and  $\beta$ -carotene (all *trans*  $\beta$ -carotene and *cis* isomers). Lutein and zeaxanthin are given combined and as single amounts. The data are sorted by the combined amount of lutein and zeaxanthin.

## APPENDIX 48. Nutritional Facts on Vitamin C

Vitamin C is a nutrient required in very small amounts to allow a range of essential metabolic reactions in the body. Vitamin C is principally known as a water-soluble antioxidant, and it prevents scurvy. It is also known by the chemical name of its principal form, L-ascorbic acid or

simply ascorbic acid. The dietary reference intakes range from 15 to 90 mg/day as shown in the following table, with a tolerable upper intake of no more than 2 g/day (2000 mg/day).

### Dietary Reference Intakes for Vitamin C for Children and Adults

<b>Age (years)</b>	<b>Males and Females (mg/day)</b>	<b>Pregnancy (mg/day)</b>	<b>Lactation (mg/day)</b>

Edible pod peas, cooked, $\frac{1}{2}$ cup	38	42
Broccoli, cooked, $\frac{1}{2}$ cup	37	41
Sweet potato, canned, $\frac{1}{2}$ cup	34	38
Tomato juice, $\frac{3}{4}$ cup	33	36.5
Cauliflower, cooked, $\frac{1}{2}$ cup	28	31
Pineapple, raw, $\frac{1}{2}$ cup	28	31
Kale, cooked, $\frac{1}{2}$ cup	27	30
Mango, $\frac{1}{2}$ cup	23	25.5

\*Daily values (DVs) are reference numbers based on the recommended dietary allowance. They were developed to help consumers determine if a food contains a lot or a little of a specific nutrient. The DV for vitamin C is 90 mg. The %DV listed on the Nutrition Facts panel of food labels states the percentage of the DV provided in one serving.

**APPENDIX 49.** Nutritional Facts on Vitamin E

Vitamin E is a fat-soluble vitamin that exists in eight different forms. Each form has its own biologic activity, which is the measure of potency or functional use in the body.  $\alpha$ -Tocopherol is the name of the most active form; it is a powerful biologic antioxidant. Vitamin E in supplements is usually sold as  $\alpha$ -tocopheryl acetate, a form of  $\alpha$ -tocopherol that protects its ability to function as an antioxidant. The synthetic form is labeled *dl*, whereas the natural form is labeled *d*. The synthetic form is only half as active as the natural form. It is important to include foods high in vitamin E on a daily basis to get enough vitamin E from foods alone. Vegetable oils, nuts, green leafy vegetables, and fortified cereals are common food sources of vitamin E.

Vitamin E deficiency is usually characterized by neurologic problems in the hands and feet, as well as peroxidation of cellular lipid membranes. Although vitamin E deficiency is rare in humans, it is likely to occur in specific situations:

1. In persons who cannot absorb dietary fat because of an inability to secrete bile or those who have rare disorders of fat metabolism
2. In individuals with rare genetic abnormalities in the  $\alpha$ -tocopherol transfer protein
3. In premature, very-low-birth weight infants (birth weights less than 1500 g, or 3 lb, 4 oz)

Most food labels do not list the vitamin E content of food. The percent daily value (%DV) listed on the table indicates the percentage of

the DV provided in one serving. The DV for vitamin E is 30 IU. A food providing 5% of the DV or less is a low source, whereas a food that provides 10% to 19% of the DV is a good source. A food that provides 20% or more of the DV provides 6 units and is considered high in vitamin E. Vitamin E content of food is stated as milligrams of  $\alpha$ -tocopherol, milligrams of  $\alpha$ -tocopherol equivalents (mg  $\alpha$ -TE), or as units on supplement labels. 1 unit = 0.67  $\alpha$ -TE in the *d* form and approximately  $\frac{1}{2}$  of that in the *dl* or synthetic form.

**Dietary Reference Intakes for Vitamin E (in milligrams) of  $\alpha$ -TE for Children and Adults**

Carrot juice, canned, $\frac{3}{4}$ cup	2.1	14
Peanut oil, 1 Tbsp	2.1	14
Corn oil, 1 Tbsp	1.9	12.5
Olive oil, 1 Tbsp	1.9	12.5
Spinach, cooked, $\frac{1}{2}$ cup	1.9	12.5
Dandelion greens, cooked, $\frac{1}{2}$ cup	1.8	12
Sardine, Atlantic, in oil, drained, 3 oz	1.7	11
Blue crab, cooked or canned, 3 oz	1.6	10.5
Brazil nuts, 1 oz	1.6	10.5
Herring, Atlantic, pickled, 3 oz	1.5	10

\*Daily values (DVs) are reference numbers based on the recommended dietary allowance. They were developed to help consumers determine if a food contains a lot or a little of a specific nutrient. The DV for vitamin E is 15 mg  $\alpha$ -TE. The %DV listed on the Nutrition Facts panel of food labels states the percentage of the DV provided in one serving.

### Sample Meal Plan

#### Breakfast

$\frac{3}{4}$  cup ready-to-eat cereal  
 $\frac{1}{2}$  cup low-fat or fat-free milk  
1 red delicious apple  
2 Tbsp peanut butter (2.5 mg vitamin E)

#### Lunch

1 cup mixed salad greens  
3 oz tuna steak  
2 slices multigrain bread  
 $\frac{1}{2}$  cup fruit salad

#### Dinner

3 oz grilled chicken breast  
 $\frac{1}{2}$  cup fresh steamed spinach (1.9 mg vitamin E)  
 $\frac{1}{2}$  cup whole grain rice  
Side salad

#### Snack

1 oz sliced almonds (7.3 mg vitamin E)  
1 Tbsp low-fat granola  
 $\frac{1}{2}$  cup low-fat or fat-free yogurt

Note: Take one multivitamin or multimineral supplement daily.

## APPENDIX 50. Nutritional Facts on Vitamin K

Vitamin K comes from the foods that we eat and the bacteria that normally reside in the intestines, which are able to make vitamin K. Antibiotics may interfere with this normal production. Other circumstances that may lead to vitamin K deficiency include liver disease, serious burns, health problems that can prevent the absorption of vitamin K (such as gallbladder or biliary disease, which may alter the absorption of fat), cystic fibrosis, celiac disease, Crohn's disease, and chronic antibiotic therapy. Excess vitamin E can inhibit vitamin K activity and precipitate signs of deficiency. The classic sign of a vitamin K deficiency is a prolonged prothrombin time, which increases the risk of spontaneous hemorrhage. Because vitamin K is stored in the liver, clinical deficiencies are rare.

Vitamin K is needed to make clotting factors that help the blood to clot and prevent bleeding. The amount of vitamin K in food may affect drug therapy, such as that from warfarin or other anticoagulants. When taking these medications, it is necessary to eat a normal, balanced diet, maintaining a consistent amount of vitamin K, and avoiding drastic changes in dietary habits.

In general, leafy green vegetables and certain legumes and vegetable oils contain high amounts of vitamin K. Foods that contain a significant amount of vitamin K include beef liver, green tea, turnip

greens, broccoli, kale, spinach, cabbage, asparagus, and dark green lettuce. Chlorophyll, which is water soluble, is the substance in plants that gives them their green color and provides vitamin K; thus chlorophyll supplements need to be considered when assessing vitamin K intake. Foods that appear to contain low amounts of vitamin K include roots, bulbs, tubers, the fleshy portion of fruits, fruit juices and other beverages, and cereal grains and their milled products.

### Dietary Reference Intakes for Vitamin K for Children and Adults

Age (years)	Males and Females (mcg/day)	Pregnancy (mcg/day)	Lactation (mcg/day)
1-3	30	N/A	N/A
4-8	55	N/A	N/A
9-13	60	N/A	N/A
14-18	75	75	75
19+	120 for men; 90 for women	90	90

Spinach, raw, chopped, $\frac{1}{2}$ cup	149	Oats, 1 oz	18
Garbanzo beans, dry, $\frac{1}{2}$ cup	132	Milk, 8 oz	10
Swiss chard, $\frac{1}{2}$ cup	123		
Beef, 3.5 oz	104	Dietary reference intake of vitamin K = 90-120 mcg.	

**APPENDIX 51.** Nutritional Facts on Calcium and Vitamin D**Calcium**

Any dietary source of calcium counts toward the daily intake, but low-fat milk or yogurt or fortified substitutes are the most efficient and readily available. Lactose-free milk and soy nut and rice drinks fortified with calcium and vitamin D are now available. In addition to milk, a variety of foods and calcium-fortified juices contain calcium and can help children, teens, and adults get sufficient levels of calcium in their diets. If it is difficult to get the recommended amounts of calcium and vitamin D from foods, a combination of food sources and supplements may be needed. Recommended dietary allowances (RDAs) were established in 2011.

**Dietary Reference Intakes for Calcium for Children and Adults**

Age (years)	Males and Females (mg/day)	Pregnancy (mg/day)	Lactation (mg/day)

<b>Asian Foods</b>		Indian ice cream (whipped soapberries), $\frac{1}{2}$ cup	130
Sea cucumber, fresh, 3 oz	285		
Soy bean curd slab, spiced, semisoft, 3 oz	269		

### Calcium Supplements

Calcium carbonate is the most common and least expensive calcium supplement. It can be difficult to digest and causes gas in some people. Taking magnesium with it can help to prevent constipation. Calcium carbonate is 40% elemental calcium; 1000 mg will provide 400 mg of calcium. Take this supplement with food to aid in absorption.

Calcium citrate is more easily absorbed (bioavailability is 2.5 times higher than calcium carbonate), easier to digest, and less likely to cause constipation and gas than calcium carbonate. It also has a lower risk of contributing to the formation of kidney stones. Calcium citrate is approximately 21% elemental calcium; 1000 mg will provide 210 mg of calcium. It is more expensive than calcium carbonate, and more of it must be taken to get the same amount of calcium.

Calcium phosphate costs more than calcium carbonate but less than calcium citrate. It is easily absorbed and is less likely to cause constipation and gas.

Calcium lactate and calcium aspartate are both more easily digested but more expensive than calcium carbonate.

### Vitamin D

Vitamin D is needed for the absorption of calcium from the stomach and for the functioning of calcium in the body. It also acts like a hormone in the body and has many functions throughout the body unrelated to its co-functions with calcium that are continuing to be discovered. Besides being in bone, receptors for vitamin D have been identified in the gastrointestinal tract, brain, breast, nerves, and many other tissues. The vitamin D in foods are micrograms of calciferol.

IU are used on supplement labels and in the 2011 RDA levels in the following table. 1 mcg = 40 IU of vitamin D or calciferol.

### Dietary Reference Intakes for Vitamin D for Children and Adults

Age (years)	Males and Females	Pregnancy	Lactation
1-3	600 IU (15 mcg)	N/A	N/A
4-8	600 IU (15 mcg)	N/A	N/A
9-13	600 IU (15 mcg)	N/A	N/A
14-18	600 IU (15 mcg)	600 IU (15 mcg)	600 IU (15 mcg)
19-70	600 IU (15 mcg)	600 IU (15 mcg)	600 IU (15 mcg)
71+	800 IU (20 mcg)	N/A	N/A

*Continued*

## APPENDIX 51. Nutritional Facts on Calcium and Vitamin D—cont'd

There are only a few food sources of vitamin D. Good sources of vitamin D are fortified foods and beverages such as milk, fortified soy, rice and nut beverages, and margarine (check the labels on these foods). Fish, liver, and egg yolks are the only foods that naturally contain vitamin D. If you do not eat vitamin D-rich foods often, you

may want to consider taking a vitamin D supplement. Most multiple vitamin supplements contain vitamin D. In addition to dietary sources, sunlight can provide the body with vitamin D because it is synthesized through the skin. Natural food sources include those listed in the following table.

### Selected Food Sources of Vitamin D

Food	Micrograms per Serving
<b>Natural Sources</b>	
Herring, 3 oz	13.83
Herring, pickled, 3 oz	5.78
Salmon, pink, canned, 3 oz	5.30
Halibut, 3 oz	5.10
Cod liver oil, 1 tsp	4.50
Catfish, 3 oz	4.25
Mackerel, Atlantic, 3 oz	3.06
Oyster, 3 oz	2.72
Shitake mushrooms, dried, 4	2.49
Sardines, Pacific, canned in tomato sauce	2.13 per $\frac{1}{2}$ cup, 1.82 per sardine
Sardines, Atlantic, canned in oil	2.03 per $\frac{1}{2}$ cup, 0.33 per sardine
Tuna, light meat, canned in oil, 3 oz	2
Shrimp, 3 oz	1.29
Egg, cooked	0.26 per whole egg, 0.25 per yolk
<b>Fortified Sources</b>	
Tofu, fortified, $\frac{1}{8}$ block	1.20
Cow's milk, all types, 8 oz	1
Milk, canned evaporated, 4 oz	1
Rice milk, fortified, 8 oz	1
Soy milk, fortified, 8 oz	1
Orange juice, fortified, 8 oz	1
Pudding, made with fortified milk, $\frac{1}{2}$ cup	0.50
Cereal, fortified, $\frac{3}{4}$ cup	0.40
Yogurt, fortified, $\frac{1}{2}$ cup	0.40
<b>Supplemental Sources</b>	
Most multivitamins for adults	Usually 10
Calcium with vitamin D	Amount varies
Vitamin D only	Amount varies

## APPENDIX 52. Nutritional Facts on Chromium

Chromium is known to enhance the action of insulin; chromium was identified as the active ingredient in the “glucose tolerance factor” many years ago. Chromium also appears to be directly involved in carbohydrate, fat, and protein metabolism; but more research is needed to determine the full range of its roles in the body. Chromium is widely distributed in the food supply, but most foods provide only small amounts (less than 2 mcg per serving). Meat and whole-grain products, as well as some fruits, vegetables, and spices, are relatively good sources, but Brewer’s yeast is by far the most concentrated food

source. Foods high in simple sugars (such as sucrose and fructose) are low in chromium. Dietary intakes of chromium cannot be reliably determined because the content of the mineral in foods is substantially affected by agricultural and manufacturing processes and food-composition databases are inadequate. Chromium values in foods are approximate and should only serve as a guide. It appears that chromium picolinate and chromium nicotinate used in supplements are more bioavailable than chromic chloride.

### Dietary Reference Intakes for Chromium for Children and Adults

Age (years)	Males and Females (mcg/day)	Pregnancy (mcg/day)	Lactation (mcg/day)
1-3	11	N/A	N/A
4-8	15	N/A	N/A
9-13	25 for boys, 21 for women	N/A	N/A
14-18	35 for boys, 24 for women	29	44
19+	35 for men, 25 for women	30	45

N/A, Not applicable.

### Selected Food Sources of Chromium

Food	Micrograms per Serving
Brewer’s yeast, 1 Tbsp or 15 g	60
Broccoli, $\frac{1}{2}$ cup	11
Grape juice, 1 cup	8
English muffin, whole wheat, 1	4
Potatoes, mashed, 1 cup	3
Garlic, dried, 1 tsp	3
Basil, dried, 1 Tbsp	2
Beef cubes, 3 oz	2
Orange juice, 1 cup	2
Turkey breast, 3 oz	2
Whole wheat bread, 2 slices	2
Red wine, 5 oz	1-13
Apple, unpeeled, 1 med	1
Banana, 1 med	1
Green beans, $\frac{1}{2}$ cup	1

### Interactions Between Chromium and Medications

Medications	Nature of Interaction
Antacids	These medications alter stomach acidity and may impair chromium absorption or enhance excretion.
Corticosteroids	
H <sub>2</sub> blockers (e.g., cimetidine, famotidine, nizatidine, and ranitidine)	
Proton-pump inhibitors (e.g., omeprazole, lansoprazole, rabeprazole, pantoprazole, and esomeprazole)	
$\beta$ -blockers (such as atenolol or propranolol)	These medications may have their effects enhanced if taken together with chromium, or they may increase chromium absorption.
Corticosteroids	
Insulin	
Nicotinic acid	
Nonsteroidal antiinflammatory drugs	
Prostaglandin inhibitors (e.g., ibuprofen, indomethacin, naproxen, piroxicam, and aspirin)	

## APPENDIX 53. Nutritional Facts on Iodine

Iodine is an important mineral that is found in a variety of foods, but it is most concentrated in foods from the ocean. It is mainly used to make thyroid hormones, which help to regulate metabolic rate, body temperature, growth, reproduction, blood cell production, muscle function, nerve function, and even gene expression. The most useful clinical tool for measuring thyroid function and thus iodine sufficiency is to measure thyroid-stimulating hormone (TSH), which is released from the pituitary gland and stimulates thyroid hormone production and release. If the TSH is high, thyroid function should be evaluated further. Selenium-dependent enzymes are also required for the conversion of thyroxine (T4) to the biologically active thyroid hormone, triiodothyronine (T3); thus deficiencies of selenium, vitamin A, or iron may also affect iodine status.

### Deficiency

Iodine deficiency is an important health problem throughout much of the world. Most of the earth's iodine is found in its oceans; thus parts of the world away from the oceans and exposed for millions of years longer have iodine-deficient soils, and large percentages of people living there can be iodine deficient unless public health measures are taken. Iodine deficiency can cause mental retardation, hypothyroidism, goiter, and varying degrees of other growth and developmental abnormalities. Iodine is now recognized as the most common cause of preventable brain damage in the world, with millions living in iodine-deficient areas.

### Dietary Reference Intakes for Iodine

Life Stage	Age	Males (mcg/day)	Females (mcg/day)
Infants	0-6 months	110 (AI)	110 (AI)
Infants	7-12 months	130 (AI)	130 (AI)
Children	1-3 years	90	90
Children	4-8 years	90	90
Children	9-13 years	120	120
Adolescents	14-18 years	150	150
Adults	19 years and older	150	150
Pregnancy	All ages	—	220
Breast-feeding	All ages	—	290

AI, Adequate intake.

The iodine contents of some common foods containing iodine are given in the following table. The iodine content of fruits and vegetables depends on the soil in which they were grown; the iodine content of animal foods, outside of those from the ocean, depends on where they were raised and which plants they consumed. Therefore these values are average approximations.

### Selected Food Sources of Iodine

Food	Serving	Micrograms per Serving	% Daily Value*
Salt (iodized)	1 g	77	51
Cod	3 oz	99	66
Shrimp	3 oz	35	23
Fish sticks	2 fish sticks	35	23
Tuna, canned in oil	3 ounces ( $\frac{1}{2}$ can)	17	11
Milk (cow's)	1 cup (8 fluid oz)	56	37
Egg, boiled	1 large	29	19
Navy beans, cooked	$\frac{1}{2}$ cup	35	23
Potato with peel, baked	1 medium	63	42
Turkey breast, baked	3 ounces	34	22
Seaweed	1 oz, dried	Variable; may be greater than 18,000 mcg (18 mg)	12

\*Daily values (DVs) are reference numbers based on the recommended dietary allowance. They were developed to help consumers determine if a food contains a lot or a little of a specific nutrient. The DV for iodine is 150 mcg. The %DV listed on the Nutrition Facts panel of food labels states the percentage of the DV provided in one serving.

The major source of dietary iodine in the United States is "iodized" salt, which has been fortified with iodine. In the United States assume that any salt in prepared foods is iodized unless the product label shows that it is *not iodized*. In the United States and Canada iodized salt contains 77 mcg of iodine per gram of salt. Iodine is also added in the diet because it is used in the feed of animals and in many processed or preserved foods as a stabilizer and a component of red food dyes. Vegetarian and nonvegetarian diets that exclude iodized salt, fish, and seaweed have been found to contain very little iodine. Urinary iodine excretion studies suggest that iodine intakes are declining in the United States, possibly as a result of increased adherence to dietary recommendations to reduce salt intake.

### Goitrogens

Substances that interfere with iodine use or thyroid hormone production are known as goitrogens and occur in some foods. Some species of millet and cruciferous vegetables (e.g., cabbage, broccoli, cauliflower, and Brussels sprouts) contain goitrogens; and the soybean isoflavones genistein and daidzein have also been found to inhibit thyroid hormone synthesis. Most of these goitrogens are not of clinical importance unless they are consumed in large amounts or there is coexisting iodine deficiency.

## APPENDIX 54. Nutritional Facts on Iron

Iron is a nutrient found in trace amounts in every cell of the body. Iron is part of hemoglobin in red blood cells and myoglobin in muscles. The role of both of these molecules is to carry oxygen. Iron also makes up part of many proteins and enzymes in the body. Iron deficiency anemia is common in children, adolescent girls, and women of childbearing age. It is usually treated with an iron-rich diet as well as iron supplements. Iron exists in foods in two forms: heme iron and nonheme iron. Vitamin C enhances the absorption of nonheme iron and should be consumed at the same time as an iron-rich food or meal. Substances that decrease the absorption of nonheme iron are:

- Oxalic acid, found in raw spinach and chocolate
- Phytic acid, found in wheat bran and beans (legumes)
- Tannins, found in commercial black or pekoe teas
- Polyphenols, found in coffee
- Calcium carbonate supplements

**Heme iron** is absorbed more efficiently than nonheme iron. Heme iron enhances the absorption of nonheme iron. The richest dietary sources of iron are from:

- Oysters
- Liver
- Lean red meat (especially beef)
- Poultry, dark red meat
- Tuna
- Salmon
- Iron-fortified cereals
- Dried beans
- Whole grains
- Eggs (especially egg yolks)
- Dried fruits

Reasonable amounts: lamb, pork, and shellfish

Iron from **nonheme sources** (as in vegetables, fruits, grains, and supplements) is harder for the body to absorb. These sources include:

Whole grains	Dried fruits
Wheat	Prunes
Millet	Raisins
Oats	Apricots
Brown rice	Vegetables and Greens
Legumes	Broccoli
Lima beans	Spinach
Soybeans	Kale
Dried beans and peas	Collards
Kidney beans	Asparagus
Nuts	Dandelion greens
Almonds	
Brazil nuts	

## Dietary Reference Intakes for Iron for Children and Adults

Age (years)	Males and Females (mg/day)	Pregnancy (mg/day)	Lactation (mg/day)
1-3	7	N/A	N/A
4-8	10	N/A	N/A
9-13	8	N/A	N/A
14-18	11 for boys; 15 for girls	27	10
19+	8 for men; 18 for women	27	9

N/A, Not applicable.

## Selected Food Sources of Iron

Food	Milligrams Per Serving	% Daily Value*
Clams, canned, drained, 3 oz	23.8	132
Fortified ready-to-eat cereals (various), ~1 oz	1.8-21.1	10-12
Oysters, eastern, wild, cooked, moist heat, 3 oz	10.2	57
Organ meats (liver, giblets), various, cooked, 3 oz <sup>†</sup>	5.2-9.9	29-55
Fortified instant cooked cereals (various), 1 packet	4.9-8.1	27-45
Soybeans, mature, cooked, ½ cup	4.4	24
Pumpkin and squash seed kernels, roasted, 1 oz	4.2	23
White beans, canned, ½ cup	3.9	22
Blackstrap molasses, 1 Tbsp	3.5	19
Lentils, cooked, ½ cup	3.3	18
Spinach, cooked from fresh, ½ cup	3.2	18
Beef, chuck, blade roast, lean, cooked, 3 oz	3.1	17
Beef, bottom round, lean, 0 in fat, all rades, cooked, 3 oz	2.8	15.5
Kidney beans, cooked, ½ cup	2.6	14
Sardines, canned in oil, drained, 3 oz	2.5	14
Beef, rib, lean, ¼ in. fat, all grades, 3 oz	2.4	13
Chickpeas, cooked, ½ cup	2.4	13
Duck, meat only, roasted, 3 oz	2.3	13
Lamb, shoulder, arm, lean, ¼ in fat, all choice, cooked, 3 oz	2.3	13
Prune juice, ¼ cup	2.3	13
Shrimp, canned, 3 oz	2.3	13
Cowpeas, cooked, ½ cup	2.2	12
Ground beef, 15% fat, cooked, 3 oz	2.2	12
Tomato puree, ½ cup	2.2	12
Lima beans, cooked, ½ cup	2.2	12
Soybeans, green, cooked, ½ cup	2.2	12
Navy beans, cooked, ½ cup	2.1	11.5
Refried beans, ½ cup	2.1	11.5
Beef, top sirloin, lean, 0 in fat, all grades, cooked, 3 oz	2.0	11
Tomato paste, ¼ cup	2.0	11

\*Daily values (DVs) are reference numbers based on the recommended dietary allowance. They were developed to help consumers determine if a food contains a lot or a little of a specific nutrient. The DV for iron is 18 mg. The %DV listed on the Nutrition Facts panel of food labels states the percentage of the DV provided in one serving.

<sup>†</sup>High in cholesterol.

Continued

## APPENDIX 54. Nutritional Facts on Iron—cont'd

### Tips For Increasing Iron Intake

The amount of iron the body absorbs varies, depending on several factors. For example, the body will absorb more iron from foods when iron stores are low and will absorb less when stores are sufficient. In addition, certain dietary factors affect absorption. Combine heme and nonheme sources of iron. Eat foods rich in vitamin C with nonheme iron sources:

- Bell peppers
- Papayas
- Oranges and orange juice
- Broccoli
- Strawberries
- Grapefruit
- Cantaloupe
- Tomatoes and tomato juice
- Potatoes
- Cabbage
- Spinach and collard greens

Drink coffee or tea between meals rather than with a meal.  
Cook acidic foods in cast iron pots, which can increase iron content up to 30 times.

### Sample Meal Plan

#### Breakfast

- $\frac{1}{2}$  cup low-fat or fat-free yogurt
- 1 whole wheat English muffin
- 1 Tbsp whipped cream cheese
- $\frac{1}{2}$  cup cantaloupe

#### Lunch

- 2 grilled steak fajitas (with mixed peppers)
- 1 oz shredded low-fat pepper jack cheese
- $\frac{1}{2}$  cup black refried beans
- Side salad with low-fat dressing

### What About Too Much Iron?

It is unlikely that a person would take iron at toxic (too high) levels. However, children can sometimes develop iron toxicity by eating iron supplements, mistaking them for candy. Symptoms include the following: fatigue, anorexia, dizziness, nausea, vomiting, headache, weight loss, shortness of breath, and grayish color to the skin.

Hemochromatosis is a genetic disorder that affects the regulation of iron absorption. Treatment consists of a low-iron diet, no iron supplements, and phlebotomy (blood removal) on a regular basis.

Excess storage of iron in the body is known as hemosiderosis. The high iron stores come from eating excessive iron supplements or from receiving frequent blood transfusions, not from increased iron intake in the diet.

To reduce the iron from dietary sources, review the list of foods and exclude or severely limit their intake until the iron overload is alleviated. Pay particular attention to sports drinks, energy bars, and fortified cereals that have significant amounts of added iron.

#### Dinner

- 3 oz grilled turkey breast
- $\frac{1}{2}$  cup mashed potatoes
- $\frac{1}{2}$  cup fresh steamed green beans topped with almonds
- 1 small whole wheat dinner roll
- $\frac{1}{2}$  cup fresh strawberries

#### Snack

- 1 med orange
- $\frac{1}{4}$  cup mixed nuts

## APPENDIX 55. Nutritional Facts on Magnesium

The mineral magnesium is important for every organ in the body, particularly the heart, muscles, and kidneys. It also contributes to the composition of teeth and bones. Most important, it activates enzymes, contributes to energy production, and helps regulate calcium levels, as well as copper, zinc, potassium, vitamin D, and other important nutrients in the body.

#### Dietary Sources

Rich sources of magnesium include tofu, legumes, whole grains, green leafy vegetables, wheat bran, Brazil nuts, soybean flour, almonds, cashews, blackstrap molasses, pumpkin and squash seeds, pine nuts, and black walnuts. Other good dietary sources of this mineral include peanuts, whole-wheat flour, oat flour, beet greens, spinach, pistachio nuts, shredded wheat, bran cereals, oatmeal, bananas, baked potatoes (with skin), chocolate, and cocoa powder. Many herbs, spices, and seaweeds supply magnesium, such as agar seaweed, coriander, dill weed, celery seed, sage, dried mustard, basil, cocoa powder, fennel seed, savory, cumin seed, tarragon, marjoram, and poppy seed.

### Dietary Reference Intakes for Magnesium for Children and Adults

Age (years)	Males and Females (mg/day)	Pregnancy (mg/day)	Lactation (mg/day)
1-3	80	N/A	N/A
4-8	130	N/A	N/A
9-13	240	N/A	N/A
14-18	410 for boys, 360 for girls	400	360
19+	400 for men, 310 for women	350	310

N/A, Not applicable.

## APPENDIX 55. Nutritional Facts on Magnesium—cont'd

### Selected Food Sources of Magnesium

Food	Milligram per Serving	% Daily Value*
Pumpkin and squash seed kernels, roasted, 1 oz	151	38
Brazil nuts, 1 oz	107	27
Bran ready-to-eat cereal (100%), ~1 oz	103	25.5
Mackerel, baked, 3 oz	97	24
Halibut, cooked, 3 oz	91	23
Quinoa, dry, $\frac{1}{4}$ cup	89	22
Spinach, canned, $\frac{1}{2}$ cup	81	20
Almonds, 1 oz	78	19.5
Spinach, cooked from fresh, $\frac{1}{2}$ cup	78	19.5
Buckwheat flour, $\frac{1}{4}$ cup	75	19
Cashews, dry roasted, 1 oz	74	18.5
Soybeans, mature, cooked, $\frac{1}{2}$ cup	74	18.5
Pine nuts, dried, 1 oz	71	17.5
Mixed nuts, oil roasted, with peanuts, 1 oz	67	17
White beans, canned, $\frac{1}{2}$ cup	67	17
Pollock, walleye, cooked, 3 oz	62	15.5
Black beans, cooked, $\frac{1}{2}$ cup	60	15
Bulgur, dry, $\frac{1}{4}$ cup	57	14
Oat bran, raw, $\frac{1}{4}$ cup	55	13.5
Soybeans, green, cooked, $\frac{1}{2}$ cup	54	13.7
Tuna, yellowfin, cooked, 3 oz	54	13.5
Artichokes (hearts), cooked, $\frac{1}{2}$ cup	50	12.5
Peanuts, dry roasted, 1 oz	50	12.5
Lima beans, baby, cooked from frozen, $\frac{1}{2}$ cup	50	12.5
Beet greens, cooked, $\frac{1}{2}$ cup	49	12
Navy beans, cooked, $\frac{1}{2}$ cup	48	12
Tofu, firm, prepared with nigari, <sup>†</sup> $\frac{1}{2}$ cup	47	11.7
Okra, cooked from frozen, $\frac{1}{2}$ cup	47	11.7
Soy beverage, 1 cup	47	11.7
Cowpeas, cooked, $\frac{1}{2}$ cup	46	11.5
Hazelnuts, 1 oz	46	11.5
Oat bran muffin, 1 oz	45	11.3
Great northern beans, cooked, $\frac{1}{2}$ cup	44	11
Oat bran, cooked, $\frac{1}{2}$ cup	44	11
Buckwheat groats, roasted, cooked, $\frac{1}{2}$ cup	43	10.7
Cod, baked, 3 oz	42	10.5
Brown rice, cooked, $\frac{1}{2}$ cup	42	10.5
Haddock, cooked, 3 oz	42	10.5
Chicken, cooked, 3 oz	38	9.5
T-bone steak, broiled, lean only, 3 oz	25	6.5
Turkey, roasted, white meat, 3 oz	24	6
Veal, cutlet, cooked, 3 oz	24	6
Beef, ground, cooked, extra lean, 17% fat, 3 oz	17	4

\*Daily values (DVs) are reference numbers based on the recommended dietary allowance. They were developed to help consumers determine if a food contains a lot or a little of a specific nutrient. The DV for magnesium is 400 mg. The %DV listed on the Nutrition Facts panel of food labels states the percentage of the DV provided in one serving.

<sup>†</sup>Calcium sulfate and magnesium chloride.

### Common and Important Magnesium-Drug Interactions

Drug	Potential Interaction
Loop and thiazide diuretics (e.g., Lasix, Bumex, edecrin, and hydrochlorothiazide)	These drugs may increase the loss of magnesium in urine; thus taking these medications for long periods may contribute to magnesium depletion.
Antineoplastic drugs (e.g., cisplatin)	
Antibiotics (e.g., gentamicin and amphotericin)	
Tetracycline antibiotics	Magnesium binds tetracycline in the gut and decreases the absorption of tetracycline.
Magnesium-containing antacids and laxatives	Many antacids and laxatives contain magnesium. When frequently taken in large doses, these drugs can inadvertently lead to excessive magnesium consumption and hypermagnesemia, which refers to elevated levels of magnesium in blood.

### Sample Meal Plan

#### Breakfast

- 1 med oat bran muffin (45 mg magnesium)
- 1 small banana
- $\frac{1}{2}$  cup low-fat or fat-free milk

#### Lunch

- $\frac{1}{2}$  cup penne pasta with the following:
  - 3 oz grilled chicken breast
  - $\frac{1}{2}$  cup fresh cooked spinach (81 mg magnesium)
  - Toasted pine nuts (71 mg magnesium)
  - 1 cup mixed salad greens topped with spinach leaves, tomatoes, shredded lettuce
  - 1 oz shredded low-fat mozzarella cheese

#### Dinner

- 2 Cajun shrimp skewers
- $\frac{1}{2}$  cup fresh steamed green beans
- $\frac{1}{2}$  cup brown rice (42 mg magnesium)
- $\frac{1}{2}$  cup fresh pineapple

#### Snack

- 1 cup soy fruit smoothie (47 mg magnesium)
- 1 oz Brazil nuts (107 mg magnesium)

Note: Take one multivitamin or multimineral supplement daily.

## APPENDIX 56. Nutritional Facts on Potassium

A potassium-rich diet is useful for cardiac patients who are trying to lower their blood pressure using diet. If diuretics are also used, it is important to know if potassium is retained or depleted, and it should be monitored. Most patients with chronic kidney disease or on renal dialysis need to be aware of the potassium in their diets. Athletes who sweat a great deal may also need attention to the potassium in their diet.

### Dietary Reference Intakes for Potassium for Children and Adults

Age (years)	Males and Females (mg/day)	Pregnancy (mg/day)	Lactation (mg/day)
1-3	3000	N/A	N/A
4-8	3800	N/A	N/A
9-13	4500	N/A	N/A
14-18	4700	4700	5100
19+	4700	4700	5100

N/A, Not applicable.

### Selected Food Sources of Potassium

Food	Milligrams per Serving	% Daily Value*
Sweet potato, baked, 1 potato (146 g)	694	19.8
Tomato paste, $\frac{1}{4}$ cup	664	18.9
Beet greens, cooked, $\frac{1}{2}$ cup	655	18.7
Potato, baked, flesh, 1 potato (156 g)	610	17.4
White beans, canned, $\frac{1}{2}$ cup	595	17
Yogurt, plain, non-fat, 8-oz container	579	16.5
Tomato puree, $\frac{1}{2}$ cup	549	15.7
Clams, canned, 3 oz	534	15.3
Yogurt, plain, low-fat, 8-oz container	531	15.2
Prune juice, $\frac{1}{4}$ cup	530	15.1
Carrot juice, $\frac{1}{4}$ cup	517	14.8
Blackstrap molasses, 1 Tbsp	498	14.2
Halibut, cooked, 3 oz	490	14
Soybeans, green, cooked, $\frac{1}{2}$ cup	485	13.9
Tuna, yellow fin, cooked, 3 oz	484	13.8
Lima beans, cooked, $\frac{1}{2}$ cup	484	13.8
Winter squash, cooked, $\frac{1}{2}$ cup	448	9.5
Soybeans, mature, cooked, $\frac{1}{2}$ cup	443	12.8
Rockfish, Pacific, cooked, 3 oz	442	12.6
Cod, Pacific, cooked, 3 oz	439	12.5
Bananas, 1 med	422	12.1
Spinach, cooked, $\frac{1}{2}$ cup	419	12
Tomato juice, $\frac{1}{4}$ cup	417	11.9
Tomato sauce, $\frac{1}{2}$ cup	405	11.6
Peaches, dried, uncooked, $\frac{1}{4}$ cup	398	11.4
Prunes, stewed, $\frac{1}{2}$ cup	398	11.4
Milk, nonfat, 1 cup	382	10.9
Pork chop, center loin, cooked, 3 oz	382	10.9
Apricots, dried, uncooked, $\frac{1}{4}$ cup	378	10.8
Rainbow trout, farmed, cooked, 3 oz	375	10.7
Pork loin, center rib (roasts), lean, roasted, 3 oz	371	10.6
Buttermilk, cultured, low-fat, 1 cup	370	10.5
Cantaloupe, $\frac{1}{4}$ med	368	10.5
1%-2% milk, 1 cup	366	10.4
Honeydew melon, $\frac{1}{8}$ med	365	10.4
Lentils, cooked, $\frac{1}{2}$ cup	365	10.4
Plantains, cooked, $\frac{1}{2}$ cup slices	358	10.2
Kidney beans, cooked, $\frac{1}{2}$ cup	358	10.2
Orange juice, $\frac{1}{4}$ cup	355	10.1
Split peas, cooked, $\frac{1}{2}$ cup	355	10.1
Yogurt, plain, whole milk, 8-oz container	352	10.0

\*Daily values (DVs) are reference numbers based on the recommended dietary allowance. They were developed to help consumers determine if a food contains a lot or a little of a specific nutrient. The DV for potassium is 3500 mg. The %DV listed on the Nutrition Facts panel of food labels states the percentage of the DV provided in one serving. Percent DVs are based on a 2000-calorie diet.

## APPENDIX 57. Nutritional Facts on Selenium

Selenium is incorporated into proteins to make selenoproteins, which are important antioxidant enzymes. The antioxidant properties of selenoproteins prevent cellular damage from free radicals. Other selenoproteins help regulate thyroid function and play a role in the immune system. Selenium, as a nutrient that functions as an antioxidant, may be protective against some types of cancer. Its role in heart disease is not clear, but it may have a preventive role.

Plant foods are the major dietary sources of selenium. The content of selenium in food depends on the selenium content of the soil where plants are grown or animals are raised. Soil in Nebraska and the Dakotas has very high levels of selenium. The southeast coastal areas in the United States have very low levels; selenium deficiency is often reported in these regions. Selenium is also found in some meats and seafood. Animals that eat grains or plants that were grown in selenium-rich soil have higher levels of selenium in their muscle. In the United States meats, bread, and Brazil nuts are common sources of dietary selenium.

Most food labels do not list the selenium content of a food. The % Daily Value (DV) listed on the label indicates the percentage of the DV

provided in one serving. A food providing 5% of the DV or less is a source, whereas a food that provides 10% to 19% of the DV is a good source. A food that provides 20% or more of the DV is high in that nutrient. It is important to remember that foods that provide lower percentages of the DV also contribute to a healthful diet.

### Dietary Reference Intakes for Selenium for Children and Adults

Age (years)	Males and Females (mcg/day)	Pregnancy (mcg/day)	Lactation (mcg/day)
1-3	20	N/A	N/A
4-8	30	N/A	N/A
9-13	40	N/A	N/A
14-18	55	60	70
19+	55	60	70

N/A, Not applicable.

### Selected Food Sources of Selenium

Food	Micrograms per Serving
Brazil nuts, dried, unblanched, 1 oz	544
Tuna, light, canned in oil, drained, 3 oz	63
Beef, cooked, 3½ oz	35
Spaghetti with meat sauce, frozen entrée, 1 serving	34
Cod, cooked, 3 oz	32
Turkey, light meat, roasted, 3½ oz	32
Beef chuck roast, lean only, roasted, 3 oz	23
Chicken breast, meat only, roasted, 3½ oz	20
Noodles, enriched, boiled, ½ cup	17
Macaroni, elbow, enriched, boiled, ½ cup	15
Egg, whole, 1 med	14
Cottage cheese, low fat 2%, ½ cup	12
Oatmeal, instant, fortified, cooked, 1 cup	12
Rice, white, enriched, long grain, cooked, ½ cup	12
Rice, brown, long-grained, cooked, ½ cup	10
Bread, enriched, whole wheat, commercially prepared, 1 slice	10
Walnuts, black, dried, 1 oz	5
Bread, enriched, white, commercially prepared, 1 slice	4
Cheddar cheese, 1 oz	4

The dietary reference intakes for selenium are 20-70 mcg.

### Sample Meal Plan

#### Breakfast

- ½ cup oatmeal (6 mcg selenium)
- 1 medium scrambled egg (14 mcg selenium)
- 1 small banana
- ½ cup low-fat or fat-free milk

#### Lunch

- 1 turkey sandwich (36 mcg selenium)
- ½ cup carrot sticks
- 1 bag baked chips

#### Dinner

- 3 oz meatloaf
- ½ cup macaroni and cheese (20 mcg selenium)
- ½ cup fresh steamed green beans

#### Snack

- ½ cup cottage cheese (12 mcg selenium)
- ½ cup fresh sliced peaches

Note: Take one multivitamin or multimineral supplement daily.

## APPENDIX 58. Nutritional Facts on Zinc

Zinc is an essential mineral that is found in almost every cell. It stimulates the activity of approximately 100 enzymes, which are substances that promote biochemical reactions in the body. Zinc supports immunity; is needed for wound healing; helps maintain the sense of taste and smell; is needed for deoxyribonucleic acid synthesis; and supports normal growth and development during pregnancy, childhood, and adolescence.

Zinc is found in a wide variety of foods. Atlantic oysters contain more zinc per serving than any other food, but red meat and poultry provide the majority of zinc in the American diet. Other good food sources include beans, nuts, certain seafood, whole grains, fortified breakfast cereals, and dairy products. Because zinc absorption is greater from a diet high in animal protein than a diet rich in plant proteins, vegetarians may become deficient if they are not monitored carefully. Phytates from whole-grain breads, cereals, legumes, and other products can decrease zinc absorption.

### Selected Food Sources of Zinc

Food	Milligrams per Serving	% Daily Value*
Oysters, battered and fried, 6 med	16.0	100
RTE breakfast cereal, fortified with 100% of the DV for zinc per serving, $\frac{3}{4}$ cup serving	15.0	100
Beef shank, lean only, cooked 3 oz	8.9	60
Beef chuck, arm pot roast, lean only, cooked, 3 oz	7.4	50
Beef tenderloin, lean only, cooked, 3 oz	4.8	30
Pork shoulder, arm picnic, lean only, cooked, 3 oz	4.2	30
Beef, eye of round, lean only, cooked, 3 oz	4.0	25
RTE breakfast cereal, fortified with 25% of the DV for zinc per serving, $\frac{3}{4}$ cup	3.8	25
RTE breakfast cereal, complete wheat bran flakes, $\frac{3}{4}$ cup serving	3.7	25
Chicken leg, meat only, roasted, 1 leg	2.7	20
Pork tenderloin, lean only, cooked, 3 oz	2.5	15
Pork loin, sirloin roast, lean only, cooked, 3 oz	2.2	15
Yogurt, plain, low fat, 1 cup	2.2	15
Baked beans, canned, with pork, $\frac{1}{2}$ cup	1.8	10
Baked beans, canned, plain or vegetarian, $\frac{1}{2}$ cup	1.7	10
Cashews, dry roasted without salt, 1 oz	1.6	10
Yogurt, fruit, low fat, 1 cup	1.6	10
Pecans, dry roasted without salt, 1 oz	1.4	10
Raisin bran, $\frac{3}{4}$ cup	1.3	8
Chickpeas, mature seeds, canned, $\frac{1}{2}$ cup	1.3	8
Mixed nuts, dry roasted with peanuts, without salt, 1 oz	1.1	8
Cheese, Swiss, 1 oz	1.1	8
Almonds, dry roasted, without salt, 1 oz	1.0	6
Walnuts, black, dried, 1 oz	1.0	6
Milk, fluid, any kind, 1 cup	0.9	6
Chicken breast, meat only, roasted, $\frac{1}{2}$ breast with bone and skin removed	0.9	6
Cheese, cheddar, 1 oz	0.9	6
Cheese, mozzarella, part skim, low moisture, 1 oz	0.9	6
Beans, kidney, California red, cooked, $\frac{1}{2}$ cup	0.8	6
Peas, green, frozen, boiled, $\frac{1}{2}$ cup	0.8	6
Oatmeal, instant, low sodium, 1 packet	0.8	6
Flounder or sole, cooked, 3 oz	0.5	4

RTE, Ready to eat.

\*Daily values (DVs) are reference numbers based on the recommended dietary allowance. They were developed to help consumers determine if a food contains a lot or a little of a specific nutrient. The DV for zinc is 15 mg. The %DV listed on the Nutrition Facts panel of food labels states the percentage of the DV provided in one serving.

### Sample Meal Plan

#### Breakfast

- $\frac{1}{4}$  cup scrambled eggs
- $\frac{3}{4}$  cup ready-to-eat breakfast cereal with 25% DV (3.8 mg zinc)
- $\frac{1}{2}$  cup sliced peaches
- $\frac{1}{2}$  cup low-fat or fat-free milk

#### Lunch

- 1 chicken salad sandwich
- $\frac{1}{2}$  cup carrot sticks
- 2 Tbsp Ranch dressing
- 1 bag baked chips

### Dietary Reference Intakes for Zinc for Children and Adults

Age (years)	Males and Females (mg/day)	Pregnancy (mg/day)	Lactation (mg/day)
1-3	3	N/A	N/A
4-8	5	N/A	N/A
9-13	8	N/A	N/A
14-18	11 for boys, 9 for girls	12	13
19+	11 for men, 8 for women	11	12

N/A, Not applicable.

#### Snack

- Yogurt, plain (2.2 mg zinc)

#### Dinner

- 3 oz grilled beef shank (8.9 mg zinc)
- $\frac{1}{2}$  cup fresh steamed peas (0.8 mg zinc)

#### Side salad

- 1 small sweet potato
- $\frac{1}{2}$  cup fresh pineapple

#### Snack

- $\frac{1}{2}$  cup Trail mix (raisins, pecans, cashews, dried cranberries)

**NOTE:** This table (taken from the DRI reports, see [www.nap.edu](http://www.nap.edu)) presents Recommended Dietary Allowances (RDAs) in **bold** type and Adequate Intakes (AIs) in ordinary type followed by an asterisk (\*). An RDA is the average daily dietary intake level; sufficient to meet the nutrient requirements of nearly all (97-98 percent) healthy individuals in a group. It is calculated from an Estimated Average Requirement (EAR). If sufficient scientific evidence is not available to establish an EAR, and thus calculate an RDA, an AI is usually developed. For healthy breastfed infants, an AI is the mean intake. The AI for other life stage and gender groups is believed to cover the needs of all healthy individuals in the groups, but lack of data or uncertainty in the data prevent being able to specify with confidence the percentage of individuals covered by this intake.

<sup>a</sup>As retinol activity equivalents (RAEs). 1 RAE = 1 µg retinol, 12 µg β-carotene, 24 µg α-carotene, or 24 µg β-cryptoxanthin. The RAE for dietary provitamin A carotenoids is two-fold greater than retinol equivalents (RE), whereas the RAE for preformed vitamin A is the same as RE.

<sup>b</sup>As cholecalciferol. 1 µg cholecalciferol = 40 IU vitamin D.

<sup>c</sup>Under the assumption of minimal sunlight.

<sup>d</sup>As α-tocopherol. α-Tocopherol includes *RRR*-α-tocopherol, the only form of α-tocopherol that occurs naturally in foods, and the 2*R*-stereoisomeric forms of α-tocopherol (*RRR*-, *RSR*-, *RRS*-, and *RSS*-α-tocopherol) that occur in fortified foods and supplements. It does not include the 2*S*-stereoisomeric forms of α-tocopherol (*SRR*-, *SSR*-, *SRS*-, and *SSS*-α-tocopherol), also found in fortified foods and supplements.

<sup>e</sup>As niacin equivalents (NE). 1 mg of niacin = 60 mg of tryptophan; 0-6 months = preformed niacin (not NE).

<sup>f</sup>As dietary folate equivalents (DFE). 1 DFE = 1 µg food folate = 0.6 µg of folic acid from fortified food or as a supplement consumed with food = 0.5 µg of a supplement taken on an empty stomach.

<sup>g</sup>Although AIs have been set for choline, there are few data to assess whether a dietary supply of choline is needed at all stages of the life cycle, and it may be that the choline requirement can be met by endogenous synthesis at some of these stages.

<sup>h</sup>Because 10 to 30 percent of older people may malabsorb food-bound B<sub>12</sub>, it is advisable for those older than 50 years to meet their RDA mainly by consuming foods fortified with B<sub>12</sub> or a supplement containing B<sub>12</sub>.

<sup>i</sup>In view of evidence linking folate intake with neural tube defects in the fetus, it is recommended that all women capable of becoming pregnant consume 400 µg from supplements or fortified foods in addition to intake of food folate from a varied diet.

<sup>j</sup>It is assumed that women will continue consuming 400 µg from supplements or fortified food until their pregnancy is confirmed and they enter prenatal care, which ordinarily occurs after the end of the periconceptional period—the critical time for formation of the neural tube.

**NOTE:** A Tolerable Upper Intake Level (UL) is the highest level of daily nutrient intake that is likely to pose no risk of adverse health effects to almost all individuals in the general population. Unless otherwise specified, the UL represents total intake from food, water, and supplements. Due to a lack of suitable data, ULs could not be established for vitamin K, thiamin, riboflavin, vitamin B<sub>12</sub>, pantothenic acid, biotin, and carotenoids. In the absence of a UL, extra caution may be warranted in consuming levels above recommended intakes. Members of the general population should be advised not to routinely exceed the UL. The UL is not meant to apply to individuals who are treated with the nutrient under medical supervision or to individuals with predisposing conditions that modify their sensitivity to the nutrient.

<sup>a</sup>As preformed vitamin A only.

<sup>b</sup>As  $\alpha$ -tocopherol; applies to any form of supplemental  $\alpha$ -tocopherol.

<sup>c</sup>The ULs for vitamin E, niacin, and folate apply to synthetic forms obtained from supplements, fortified foods, or a combination of the two.

<sup>d</sup> $\beta$ -Carotene supplements are advised only to serve as a provitamin A source for individuals at risk of vitamin A deficiency.

<sup>e</sup>ND = Not determinable due to lack of data of adverse effects in this age group and concern with regard to lack of ability to handle excess amounts. Source of intake should be from food only to prevent high levels of intake.

**NOTE:** A Tolerable Upper Intake Level (UL) is the highest level of daily nutrient intake that is likely to pose no risk of adverse health effects to almost all individuals in the general population. Unless otherwise specified, the UL represents total intake from food, water, and supplements. Due to a lack of suitable data, ULs could not be established for vitamin K, thiamin, riboflavin, vitamin B<sub>12</sub>, pantothenic acid, biotin, and carotenoids. In the absence of a UL, extra caution may be warranted in consuming levels above recommended intakes. Members of the general population should be advised not to routinely exceed the UL. The UL is not meant to apply to individuals who are treated with the nutrient under medical supervision or to individuals with predisposing conditions that modify their sensitivity to the nutrient.

<sup>a</sup>Although the UL was not determined for arsenic, there is no justification for adding arsenic to food or supplements.

<sup>b</sup>The ULs for magnesium represent intake from a pharmacological agent only and do not include intake from food and water.

<sup>c</sup>Although silicon has not been shown to cause adverse effects in humans, there is no justification for adding silicon to supplements.

<sup>d</sup>Although vanadium in food has not been shown to cause adverse effects in humans, there is no justification for adding vanadium to food and vanadium supplements should be used with caution. The UL is based on adverse effects in laboratory animals and this data could be used to set a UL for adults but not children and adolescents.

ND = Not determinable due to lack of data of adverse effects in this age group and concern with regard to lack of ability to handle excess amounts. Source of intake should be from food only to prevent high levels of intake.
